D. GLUMACEUM is the best known of all, and a sweetly-scented, beautiful species. The spikes are larger and longer than those of any other kind, of a yellowish white tint that, though not very showy in individual flowers, is distinctly pretty in the aggregate. It flowers during the early spring months, and was introduced at or about the same time as the last-named and by the same firm of nurserymen, with whom it flowered in 1840.

D. UNCATUM is a more recently introduced species, having been imported by Messrs. Hugh Low and Co. from some of the islands about the Malay Peninsula. In colour of the flowers and also in habit it most resembles *D. filiforme*, but the racemes are stouter and shorter, not so elegant or so bright in colour.

Angraecum articulatum.—This I have recently noted doing well and flowering freely in a neighbouring collection. The pretty white blossoms on stout, arching scapes are very useful just now, but this can hardly be looked upon as its proper flowering season. It is best grown in small wooden baskets, as advised for dwarf *Phalenopsis*, the only compost necessary being a little Sphagnum Moss and charcoal or crocks. Keep this as sweet and clean as possible, and give plenty of water all the year round, only avoiding a soaked condition of the Moss during winter. It was introduced from Madagascar by Mr. Ellis, and first flowered about 1871.—H.

Odontoglossum Lindleyanum.—This is a very variable species, some few of the varieties being very poor, but a good form of it is a really fine garden Orchid. Such an one I noticed during the week; it had a spike nearly 2 feet in length, the individual blossoms being about 3 inches across, pale yellow on the sepals and petals, with one large and several smaller brown blotches. The lip has white side lobes, the centre one yellow and brown. It is a native of New Grenada, and

was introduced by the Royal Horticultural Society, in whose garden at Chiswick it first flowered in 1864. In habit and cultural requirements it is almost identical with *O. crispum*.—H. K.

Oncidium concolor.—I have noted this pretty species flowering in several collections quite recently, and of course entirely out of season. As a cultivator one never likes to see Orchids flower except at the proper time, but such beautiful blossoms as these would be very acceptable at this time of year were it its due season. Probably if this species were introduced in large quantities like some of the more popular *Odontoglossums*, for instance, we should see it in flower almost every month in the year, and as I have before pointed out the season does not affect cool-house kinds quite in the same manner as it does those species that need a dry and wet period of rest and growth respectively. *O. concolor* requires perhaps as regular a temperature all the year round as any Orchid in existence, its habitat being quite an alpine one on the Organ Mountains of Brazil. All available light in winter and a constantly cool, shady and moist house for its summer treatment suit it perfectly.—H. K.

Cycnoches chlorochilon.—There is a very considerable difference in the flowers on various plants of this fine Orchid, some occurring only a few on the spike, but large individually; others smaller, but occurring in larger numbers. All have the same typical column, from which the popular name of Swan's-neck Orchid has been given, and the colour varies only a shade or two, being a lighter or darker yellow in different plants. The blossoms on some plants are pleasantly scented; in others there is little scent. Its culture is not difficult, the principal points being to grow it strongly by potting or basketing—the latter for preference—in a sound and substantial compost which will retain the abundant moisture the roots delight in. A good proportion of loam may with advantage be added to the usual mixture for epiphytal plants, the drainage must have special attention, and in planting see that the large heavy bulbs have some support until roots are freely produced. Water freely at the root while growing, but if overhead sprinkling is practised, see that the water does not lodge in the forming growth. Though deciduous, the foliage should be retained as long as possible and the plant kept well up to the light in autumn.

Cypripedium insigne Chantini.—This is usually among the earlier of the *insigne* varieties to open, and certainly one of the best. The flower is not perhaps as a rule so large as that of *C. i. Manleyi*, but it is better set up, has a broader and better formed dorsal sepal, and the white marking runs nearly to the base on each side, the purple spots coming about half way up in the centre. Like many others of this class, it is not seen in its best form in weak, half-starved plants, such as are common in many collections; to grow it well it requires very liberal treatment, and until the plants reach specimen size they should be repotted at least once in two years. I have frequently had flowers of this and other varieties sent me with queries as to what was wrong, the flowers being only about half the normal size and very poor in colour. This was in most instances due to nothing else but starvation treatment. The plants must be grown in good loam fibre, peat, and chopped Sphagnum, these being kept open by the addition of crocks and charcoal. The drainage should be free and the water supply ample all the year round. Grow it in a moist greenhouse temperature, and when the growth is complete, place the plants in a good light and bring them on in batches for flowering.—H.

Trichosma suavis.—I noticed some very fine plants of this species recently, and it is apparently getting far more plentiful and better cultivated than formerly. There are fewer of the short undeveloped growths, and consequent weak flower-spikes, that hardly show above the foliage. This is caused by the plants being starved, and is also frequent upon plants not properly established or

otherwise weak. When it is evident that the flower-spikes are not going to lengthen properly, they should be pinched out, as it is useless wasting the energies of the plants upon unsightly abortive-looking flowers. The plant is very nearly related botanically to the *Celogynes*, and, like these popular plants, delights in a very free and open compost. The peculiar roots appear to me to have a strange affinity for Sphagnum Moss, and rather more of this than peat may with advantage be used in its cultivation, adding thereto plenty of large, rough lumps of charcoal. The habit of the plant is to grow in a close tuft, and consequently it takes a number of years to make a large specimen. The best position for it is in quite a cool house, with plenty of atmospheric moisture during the whole of the year, excepting just when the flowers are open. Its native home is high up on the Khasia Hills, and here it was discovered by Gibson when collecting Orchids for the Duke of Devonshire in 1837.—H. R.

VANILLA PLANIFOLIA.

The blossoms of this Orchid are rather unattractive, but it is the most useful of the species that have an economic value as distinct from their flowering qualities. The pods, obtained by artificial fertilisation, are in request for flavouring; they have a rich aroma when fully ripe, which, however, they soon lose to a great extent unless means are taken to prevent it. Imported pods arrive as a rule in protective material, as tinfoil or lead, and probably this would answer well for cultivated specimens. I lately saw a fine lot of large pods in one of the houses at Syon House, where the plant is very successfully cultivated. They are in bunches of five or six, and many of them are 7 inches and upwards in length. It would make an interesting plant for amateurs to grow, especially those who have back walls and similar places at present bare of foliage or anything else. To get plenty of fruit the position must not be too heavily shaded or dark. As freedom of flowering depends largely upon the growth being solid and hard, the plants need only be very lightly shaded at any time, while during the autumn and winter the glass above them should be clean, and every ray of light possible should reach the plants. The method of procedure at Syon is apparently to bring on plenty of young wood by planting young, healthy pieces and cutting away some of the older shoots. Anyone wishing to cover a wall quickly could not do better than obtain a few healthy, well-rooted young plants and prepare a narrow border, say about 6 inches wide, for their reception. This may be bricked, or the plants may be set in boxes or troughs made for the purpose. There must be an outlet for superfluous water, and in addition abundance of clean broken crocks for drainage, as, though roots are plentifully produced, only a few of these enter the lower compost, those higher up preferring to take hold of a brick wall or anything that happens to come in their way. Personally, I like to establish the young plants in small pots before setting them out, as I have found in a few cases when planted just as cut off that they did not start regularly. I have found, too, that a little additional warmth after they are cut from the parent plant gives them a start, and this is easily provided when pots are used at first. Where a little bottom-heat can be turned on under the border or boxes, there is not, of course, so much need for it. After planting, a brisk temperature may be kept up and plenty of growth got into the plants by early closing and judicious use of fire-heat. The night temperature should be kept up to 65° on cold nights by fire-heat, advancing this by degrees as the days

lengthen. By April or May a few flowers may be produced, and these should be fertilised. If a good set can be obtained, it is as well not to set any after midsummer, and a slightly dry atmosphere should be maintained in the house until the pods begin to swell. Then push on the moisture and warmth until the end of August, when a slight diminution in the latter may be made. The plants, as they grow, need some support, of course, and this, in the case of Mr. Wythes' plants, is effected by running wires horizontally at a distance of 4 inches or so from the wall. Their very thriving appearance and the large number of pods produced prove the treatment accorded to be correct. H. R.

Masdevallia racemosa.—This is one of the most distinct of Masdevallias, a plant not by any means common in cultivation, and one that would be well worth importing in quantity if it could be done. The plant, instead of producing single-flowered scapes, throws up a tall semi-erect raceme carrying a dozen or more bright orange-crimson flowers, each about 1½ inches across. The plant is a native of New Grenada, and was

chaste and beautiful little bloom, and a welcome addition to any collection of Orchids. Here it does remarkably well in a house devoted principally to Ferns, but containing also such Orchids as *Odontoglossum grande*, *O. citrosimum*, and several of the larger-growing *Cymbidiums*. Many growers do it well in the Cattleya house, proving that it likes more heat than most *Odontoglossums*. The plants should be placed in medium-sized pans or baskets and suspended near the roof, where they get the full advantage of light in winter and the best of the air currents in summer. *O. Krameri* and its varieties are natives of Costa Rica, whence M. C. Kramer sent the typical plant to Messrs. Veitch in 1868.—H. R.

Cattleya Bowringiana.—I noticed a finely-flowered specimen of this pretty *Cattleya* at Syon House the last week in September, this being a good deal earlier than its usual flowering season. The plant had evidently been in bloom some time, and for a place so near the metropolis it is doubtless a great advantage to have it flowering thus early. The delicate flowers, so bright and effective, are, of course, of the utmost value during dull November, but it is better to have

Water Lilies in lower ponds at St. James's, West Malvern. From a photograph sent by Mr. A. Dean. (See p. 367.)

named by Dr. Lindley from specimens collected many years before it was introduced to cultivation, as far back as 1839 in fact. The first living plants that reached this country were collected by Mr. Carder in 1883, and it is now seldom seen in any quantity. Its culture does not differ materially from that given to other *Masdevallias*, as it thrives in a cool, moist house all the year round, likes a thin compost and a regular water supply.

Odontoglossum Kramerii album.—I have noticed some nice plants of this in flower during the week, and this pretty variety seems to be getting more plentiful. In place of the pale purple-rose of the typical flowers the variety has them pure white with only a yellow centre in the lip, a

them in September than have them ruined by the fog at the later date. Some two or three years ago I mentioned plants of this species that I had seen doing well under warmer conditions than are usually given it, and the only fault of the warmer treatment is that the flowers are produced too early. In country districts where the air is pure even November fogs are not to be feared, but it is quite different near London. I have noticed that many of our most successful growers in the latter neighbourhood report their plants before flowering, when the young roots are only just appearing, a proceeding that suits the plants well, but it is bad, perhaps, for the flowers. I can confidently recommend amateur growers around London giving this species

rather more warmth than the majority of Catleyas, for the reason noted above; it will not harm the plants in the slightest degree. They are, in fact, all the better for it, while those country readers who have a difficulty in keeping up a display in autumn will also find it to their advantage. The plant is a native of Honduras, and was introduced about fourteen years ago by Messrs. Veitch and Son.—H.

Oncidium loxense.—I recently noted this uncommon species in flower, and this is much later in the season than I have seen it before. The spike was about 4½ feet in length and the individual flowers upwards of 3 inches in diameter. It is certainly one of the finest of the *O. macranthum* section. It comes from Ecuador, and thrives in company with cool house kinds generally, liking a fairly large pot and a very rough, open compost consisting of peat, Moss, and roughly broken charcoal and corks. Though discovered as far back as 1842, it was probably never in cultivation until quite recent years, and is even now a rare plant.—H.

DESTROYERS.

BEEES AND FRUIT.

THE correspondence published last week makes it quite clear that in some localities bees have given trouble as attackers of fruit. Lest, however, it should be thought that the evidence is all on one side, I will ask you to be good enough to publish the letter from a resident in Herefordshire which I enclose, typical of others which have been kindly sent me. It will be seen that bees differ widely in this respect, an interesting peculiarity owing, doubtless, as suggested by Mr. Archer-Hind, to the varying conditions of their natural food supply. Next to the preservation of a healthy and fertile queen, the leading instinct of the honey-bee is the storage in abundant quantities of the sweet and aromatic nectar produced by many flowers for its benefit, or that of other fertilising insects. For this nectar the sub-acid juice of our ordinary fruits must be but a sorry substitute, and its storing qualities even when ripened in the hive are probably indifferent. The past year has been in many places very unfavourable to the production of honey, and in the absence of flower-nectar bees have been driven to collecting honey-dew. This is of two kinds, one being an exudation from the leaves of various trees under unhealthy conditions, the other a secretion of leaf-juices by aphids. This latter is the source of the black, mawkish, so-called honey which has been produced this season in many districts. It is probably no more palatable to bees than to human beings, and on this supply, in its turn, failing, they are led to attack fruit. With me, no honey-dew was collected, and although my hives were close by walls on which Peaches, Figs, &c., could with great difficulty be preserved, owing to the persistent attacks of wasps and blue-bottle flies, the bees remained as usual perfectly indifferent to fruit, and while the greenhouse often contained many bees, the vinery next door was free from them. It may be confidently expected that in a year less unfavourable to our honey-gatherers, few gardeners will have to complain of their depredations, which, indeed, are a small matter when we consider that, in addition to their great value as fertilising agents, we are, as modern science teaches us, indirectly indebted to these useful insects and their kindred, under a kindly Providence, for the wealth of brilliant flowers that adorn our gardens.—H. J. O. WALKER (Lt.-Col.), *Lexford, Bullleigh Satterton.*

"For at least twenty years I have kept bees, and now have fifteen hives. I am passionately fond of my garden and spend all my spare time there. I grow Grapes and Peaches in my houses, and outside Peaches, Apricots, Figs, Plums, Green Gages, Pears, and Apples in quantity, but never once have I seen a bee attack them. My gardener says, 'I never saw bees attack fruit, and they have plenty of chance here, but I will take more

notice in future.' All I can say is that here, at any rate, it is a libel on the bee."—SENEKER H. BURHAM, *Underdown, Ledbury.*

—The notes that have appeared in THE GARDEN anent these are interesting, especially to those who, like myself, keep several hives. For several seasons I have found bees attack the Plums. In my own case they have not injured any fruit but Plums. When they take to them they are severe. I have noticed bees never touch fruit as long as they can obtain honey from flowers. I am under the impression they are from hives where the store of honey is low, or where the honey has been taken from them. I consider bees useful in the garden, and if more were kept we should not hear so much of fruit setting badly.—J. CROOK.

Bullfinches and Gooseberry trees.—Bullfinches are so numerous in the much-wooded neighbourhood of Oundle, Northamptonshire, as to be a perfect nuisance to gardeners and cottagers. All manner of preventive methods have to be adopted in order to save Gooseberry buds from destruction. But even supposing the Gooseberry trees to be saved, there are certain Plums these birds are very partial to, and these easily fall a prey to them. In infested districts it is very little use planting the Cherry Plum, as bullfinches make such a raid on the buds. In spite of the frequent pleas put forward on behalf of the poor bullfinch, one cannot wonder at the gardener or cottager shooting it.—C.

Earwigs.—In answer to a query as to the best means to be employed for the destruction of earwigs, I regret my inability to offer any other remedy than traps of various descriptions used as early in the season as possible. My remarks were directed solely to their attacks on wall fruit. On old walls, however, that bear the scars of nearly 200 years, earwigs are very numerous, and in nine seasons out of ten I should hardly have a sound Peach, Nectarine or Apricot if they were not trapped immediately they make their appearance. This early trapping is the secret of success so far as walls are concerned. I left it one season until the fruit was approaching the ripening stage, and although thousands of the insects were then destroyed, there appeared to be no end to their numbers, and most of the fruit was tapped. After that experience I have invariably placed the traps in position early in July, and, as stated in the note, very nearly a clean sweep is made of them before the softening of the fruit. Where the giant Reed (*Arundo donax*) is available, it is preferable to Bean stalks as a trap. Short lengths of the former preserve their straightness, and the interior being smooth the insects are the more easily dislodged. Writing of insects reminds me to note in connection with wasps that nearly one hundred nests have been destroyed within a half-mile radius, taking the garden as a centre.—E. BYRELL.

A note from the S.W. of Scotland.—The weather here, with the exception of a few days, about the 15th, 16th and 17th of October, when a bitter east gale prevailed, doing much injury to exposed plants, has been very mild. To day (Oct. 23) Hydrangeas and such hardy Fuchsias as Riccartoni, coccinea, and M. Lemoine's new hybrid, Bouquet, are still in bloom with the little *F. pumila*. *Cistus corbariensis* is yet in flower together with a few single and double Helianthemums. Roses are in bloom, among them the old double white, Reine Marie Henriette, Alistar Stella Grey, Mme. Isaac Pereire and others. Autumn Crocuses and double Meadow Saffrons are plentiful. Phloxes are yet in bloom with Japanese Anemones, a number of Michaelmas Daisies, and Moon Daisies. *Phygelius capensis* is finer than earlier in the season. *Erica carnea* has begun to show colour and promises well for an early bloom. *Galanthus cilicicus* is well through the ground, and Mr. Whittall's new giant Snow-drop is also showing. *Eccremocarpus scaber* is still flowering, and near by some of the Clematises are covered with their feathered seeds. In the

rock garden *Plumbago larpentae* is yet bright, and *Erodium supraeanum* gives a few of its delicately coloured flowers. Here and there are little patches or spots of colour, with late flowers or second blooms on alpine, and the bright green of the foliage of many of these is very pleasing. Dahlias, Tropaeolums and Sweet Peas are not yet cut down and annuals are still in bloom. S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

The weather in West Herts.—During the past fortnight there has not been a single unreasonably cold day and only one cold night, so that the warm period known as "St. Luke's little summer," which often occurs in the latter half of October, may be said to have been unusually well marked this year. On the cold night in question the exposed thermometer showed 6° of frost, making this the coldest night as yet this autumn. My Dahlias were only very slightly injured by this frost, just a few of the upper leaves being discoloured by it. At 1 foot deep the ground is now about 1° warmer, and at 2 feet deep about 3° warmer than is seasonable. Rain fell on two days to the total depth of rather more than half an inch. On the 1st the sun shone for seven hours, which is a high record for a November day. The past month was the warmest October of which I have any record. October, 1886, was, however, very nearly as warm. As regards temperature, the most noteworthy feature was the number of warm nights and the absence of unusual cold on any of them, the exposed thermometer at no time indicating more than 3° of frost. Rain was measured on fifteen days to the aggregate depth of 2½ inches, which is nearly half an inch below the average for the month. In the same month in 1891 the fall was 8 inches. The sun shone on an average for 2½ hours a day, or about an hour a day less than the October mean.—E. M., *Berkhamsted.*

SOCIETIES AND EXHIBITIONS.

NATIONAL CHRYSANTHEMUM SOCIETY.

FLORAL COMMITTEE.

ON Monday last at the Royal Aquarium there was a meeting of the floral committee, when Mr. T. Bevan occupied the chair. As might be expected, there was a fairly full attendance of members, and a considerable amount of work was done in adjudicating upon the number of exhibits submitted. The principal contributions came from Messrs. H. Cannell and Sons, N. Molyneux, W. Wells, W. J. Godfrey, R. Owen, H. J. Jones, W. Seward, H. Weeks, and several others, whose total made a very excellent display, and it was a subject of remark that there was a high standard of quality in all the exhibits.

First-class certificates were awarded as under—

CHRYSANTHEMUM SIR HERBERT KITCHENER.—A very large Japanese, with medium-sized florets; colour bright golden-chestnut-bronze, with a golden reverse; florets long and drooping. Staged by Mr. R. Owen.

CHRYSANTHEMUM JOHN MILES.—An incurved flower, very perfect in form, deep and globular; colour rich golden-orange. From Mr. N. Molyneux.

CHRYSANTHEMUM MRS. COOMBS.—A Japanese with very long drooping florets, very full and double; colour deep rosy mauve. From Mr. H. Weeks.

CHRYSANTHEMUM LADY CRAWSHAW.—A large Japanese with narrow intermingling florets; colour creamy white, slightly tinted. From Mr. H. Weeks.

CHRYSANTHEMUM EMILY TOWERS.—A Japanese with medium-sized florets, incurved in the centre; rosy mauve-pink, with pretty silvery pink reverse. From Mr. Weeks.

CHRYSANTHEMUM HENRY WEEKS.—A Japanese of large size with medium florets, the outer ones purplish crimson, inside reddish crimson, golden reverse. Shown by Mr. Wells.

CHRYSANTHEMUM MRS. WHITE-POPHAM.—A very large Japanese incurved, with very broad, grooved florets, bold and effective; colour white, deeply shaded rosy purple. From Mr. W. Wells.

CHRYSANTHEMUM MRS. W. MEASE.—The well-known Mme. Carnot sport, much paler than G. J. Warren. It is as beautifully formed as its parent, Mme. Carnot, and the colour is a pure pale sulphur or primrose. Exhibited by Mr. Godfrey.

CHRYSANTHEMUM NELLIE POCKETT.—This is of Australian origin, a very fine Japanese incurved, with narrow grooved florets; colour pure glistening white. Shown by Mr. W. Wells.

CHRYSANTHEMUM MYTCHETT BEAUTY.—A golden yellow decorative Japanese, very free and useful. From Mr. Wells.

CHRYSANTHEMUM R. HOOPER PEARSON.—This is a large Japanese, big and solid, a kind of yellow Mutual Friend, with very broad florets, curly at the tips. The colour is a deep velvety golden yellow, with a reverse of glistening pale gold-yellow. From Mr. H. J. Jones.

CHRYSANTHEMUM RYECROFT SCARLET.—This is a very useful decorative, free-flowering Japanese. The colour is crimson-red, with golden reverse. From Mr. H. J. Jones.

Some very good varieties submitted to the committee hardly came up to the standard required. Of these, Fred. Jones, a fine crimson Japanese with golden reverse; Fair Maid, a flat Japanese, of a pretty shade of lilac-pink; Jane Bloomfield, a very fine shade of golden yellow; and Le Grand Dragon, a deep golden yellow, the committee wished to see again.

Apart from those specially noticed by the committee, we think Jane Molyneux, a fine long-petalled, white Japanese; Miss Mary Leschelles, the white sport from Reine d'Angleterre, and several others will be heard of again.

On Monday evening last the executive committee of this society held a meeting at Carr's Restaurant, Strand, when Mr. T. W. Sanders occupied the chair. Some time was occupied in disposing of the minutes of two previous meetings and of correspondence relating to various matters that had arisen since. After this the chairman gave in a report from the sub-committee appointed to take the necessary steps to defend the action recently brought against the society, and which resulted in a verdict in its favour. A vote of thanks was accorded to Messrs. Sanders, Harman-Payne, and A. Taylor for their trouble in acting as this committee. It was announced that the classification committee would meet at 1 o'clock on the first day of the forthcoming November show. The secretary then reported that the prize-money, £47 5s., awarded at the October show had been paid, and the committee confirmed the awards of the arbitration committee to the miscellaneous exhibits on that occasion. The report of the dinner sub-committee was next presented. It was recommended that it take place at the Holborn Restaurant on Wednesday, November 30, and that ladies be invited. The charge will be five shillings. Regarding the fixtures for 1899, it was resolved that the shows be as follows: October 10, 11 & 12, November 7, 8 and 9, and December 5, 6 and 17, and that no September show be held. Arrangements as to stewards, judges, luncheon, &c., brought the meeting to the end of the agenda paper, and after the election of twenty-three members and one Fellow the meeting broke up.

Royal Horticultural Society.—The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, November 8, in the Drill Hall, James Street, Westminster, 1 to 4 p.m. A lecture on "Some of the Plants Exhibited" will be given by the Rev. Prof. Geo. Henslow, M.A., at 3 o'clock.

Royal Gardeners' Orphan Fund.—The executive committee met at the Horticultural Club on the 28th ult., Mr. William Marshall presiding, when the following special donations were

announced: Ealing Gardeners' Society, £15; Sandringham Estate Cottage Garden Society, £5 5s.; Mr. R. McLachlan, Lewisham, £5 5s.; Trentham Horticultural Society, per Mr. P. Blair, £5; Miss Faulkner, Wimbledon Horticultural Society, £5; Mr. J. Selway, Betteshanger, £2 15s.; Mr. A. D. Christie, opening The Gardens, Ragley, Alcester, £1 13s.; Hessele Gardeners' Society, £1 4s. 1d.; Earl Dysart, £1; Mr. C. Sutton, Chevening Park (box), 15s. 6d.; Mrs. Wills, 16, Onslow Crescent, S.W. (box), 12s. 6d.; Mr. W. Miles, Southampton (box), 11s. 9d.; Mr. Parker, Stroud, 10s. 6d.; Mr. H. Burbidge, Westgate, 10s.; Mr. N. Kneller, Malshanger (box), 7s. 6d.; and Mr. J. Bendell, Ringwood, 10s. 6d. Letters were read from the mothers of children who had ceased to be chargeable to the fund, owing to the operation of the age limit, bearing testimony to the great assistance afforded to them by the fund at a time of great necessity. It was resolved that the annual general meeting of subscribers to the fund and election of children should take place on February 17 next.

PUBLIC GARDENS.

A new garden off Russell Square.—A letter has been issued from the Bedford Estate office, addressed to the local authority (the St. Giles District Board of Works) and others interested, intimating that as the leases of the premises in Montague Mews and Southampton Mews, Russell Square, are about expiring, his Grace proposes to pull down the stables and close the mews. The site is to be converted into a garden for the use of the tenants on the estate in the neighbourhood, very few of whom use the stables, a number of which have been let to jobmasters of late years.

Hampstead Heath extension.—The Marylebone Vestry have sent to the London County Council and the Paddington, the St. Pancras, and the Hampstead Vestries a resolution "that, in view of the many reports current as to the contemplated use of the Golden's Hill estate, they are of opinion that the interests of the public would be best served by the beautiful grounds being preserved as nearly as possible in their present state, the residence of the late Sir Spencer Wells being used as a museum and refreshment rooms under the same regulations as the Waterlow Park estate."

The value of fowls' manure.—Manure from fowl-houses, and also that from pigeon-lofts, is often ruthlessly thrown away, whereas it might be put to good use in the garden. One good Primula grower I knew always used it for his plants, mixing it when in a dry state with the potting soil. When perfectly dry it is easily reduced to a powder. It must be used in moderation, being very strong. The same grower used also to throw a bagful of the manure into a tub of water and water the Primulas when in full growth with the liquid, taking care to dilute it sufficiently. The vigour of the plants and the size and colour of the bloom-trusses testified to its suitability as a fertiliser. This manure is also well suited for applying to plots of Turnips, particularly early crops, as, being of a heating nature, it promotes a speedy growth. For small border sowings a little of the manure may well be dug in, later on giving a sprinkling between the rows, and afterwards loosening the surface with the Dutch hoe. Rain, or in dry weather artificial waterings, will do the rest.—NORWICH.

Paris Universal Exhibition, 1900.—The plans of the horticultural section at the Paris Exhibition of 1900 are now complete, and it promises to be a very attractive building. Space has been secured for British exhibitors, and it is hoped that it will be filled in a manner to reflect credit on horticulture in this country. It is understood that there will be periodical shows of flowers

and fruit during the continuation of the exhibition. A sub-committee of the Royal Commission composed of the following gentlemen has been formed: Sir J. Trevor Lawrence, Bart., Sir Edward Grey, Bart., M.P., Mr. W. T. Threlton-Dyer, Dr. Masters, Dr. Schlich, Mr. T. A. Dorrrien-Smith, and Mr. Harry J. Veitch, who is to be the honorary secretary to the sub-committee. Any communications may be addressed to him or to the secretary, Royal Commission, Paris Exhibition, St. Stephen's House, Westminster, S.W.

OBITUARY.

MR. LATIMER CLARK.

It is with very deep regret I record the death of this gentleman, which took place very suddenly at his residence, The Grove, Kensington. As a civil and electrical engineer Mr. Clark was known throughout the world, but as a gardener, and especially as a lover and grower of the choicest alpine, bulbous and bog plants, he was equally well known. When living some years since on the highest part of Sydenham Hill, Mr. Clark's garden was among the most picturesque I have seen, scarcely a department in hardy plant gardening being left untouched. The usual method of summer bedding found no favour with him, but the banks of Rhododendrons, beds of choice American plants, and countless beds of hardy bulbous and herbaceous plants generally absorbed much of his spare time. It was a garden full of treasures, in which it was difficult to particularise. The rock garden, and equally the bog garden, received considerable attention, and not least of the many things in which Mr. Clark took especial interest was the embellishing of several acres of woodland with suitable subjects. Of Narcissi and Croci he had at one time choice collections, and in his Sydenham garden *Narcissus maximus* was a thing to remember by those who saw it in flower. Giant masses of Christmas Roses, the solid tufts over 2 feet through and of the major variety, could scarcely be surpassed, and were justly treasured by their owner. Hardy Ferns, too, and aquatics all received adequate care and attention. A somewhat interesting, if not indeed a unique, feature of the garden here noted was the great extent of wall gardening practised in every direction, the walls being pocketed on the top to receive soil, and in this way a great number of hardy plants were grown with success. Mr. Clark was a Fellow of the Royal Horticultural Society and a regular visitor to the fortnightly meetings, ever on the alert to obtain anything new or meritorious among the subjects he knew and grew so well.

E. J.

Endurance of Bamboo stakes out of doors.—Have any of your readers any experience of the endurance of Bamboos in gardens whether as espaliers or as stakes? I have heard they endure much longer than any of our own native woods.—E. T. L.

Hybrid failures.—I shall be greatly obliged to any raisers of hybrids or varieties by crossing (not spontaneous seedlings) who will tell me of any species which failed to take the pollen of any other species, or of any variety of a species which could not be fertilised by crossing it with some other variety or species. I should like also to record any plants which could not be fertilised by their own pollen or with pollen of other plants of the same species.—GEORGE HENSLOW, 80, Holland Park, W.

Table decorations (J. B. B.).—"Table Decoration." By Wm. Low. Messrs. Chapman and Hall, London.

Names of plants.—*F. S. Fowler.*—1, Marvel of Peru (*Mirabilis Jalapa*); 2, *Elaeagnus longipes*; 3, *Elaeagnus reflexa aureo-variegata*.

Names of fruit.—*Bucks.*—Pears: 1, Beurré Sterckmans; 2, Marie Louise; 3, Beurré Diel. Apples: 4, Abbey Waltham Seedling; 5, Lord Derby; 6, Winter Hawthornden.—*T. S. Robinson.*—Apple Northern Greening.

THE MARKET GARDEN.

FERNS FOR MARKET.

THE demand for Ferns seems yearly to be on the increase, and although nurseries devoted almost entirely to their culture are on the increase, the supply does not appear to exceed the demand, at least not for well-grown stock. The plants consist chiefly of such sorts as are well known, and it requires some time to get buyers to take anything new. It is surprising how few out of the vast number of varieties are appreciated for general market work. The Ferns are used in various sizes, from tiny plants in 2-inch pots up to large plants in 6-inch pots. Some are grown on into 8-inch pots, but there is little demand for these generally. Of course they do not make much advance in growth after they come into use for decoration, but they stand better than when grown in larger pots. Over-watering is often a fault with people who do not understand plants, but with large plants in small pots it is difficult to err in that way. Of Adiantums, *A. cuneatum* is still more extensively grown than any other variety both for pots and cutting. The next to this is *A. elegans*, which has rather larger fronds and grows more erect. A great advantage in this variety is that it is hardier than *A. cuneatum*, and will grow better during the winter. For cutting it is considered by many to be far superior to the older variety. *A. Farleyense* in the hands of market growers has proved a valuable variety. Being grown fully exposed to the light, it stands much better than when grown under heavy shading. Of course it is only for special work that it can be used, and it is not profitable to grow for cutting from, for the new fronds do not come freely after the plants have been denuded of their mature ones. *A. scutum* or *tenerum* is a very popular variety. *A. Rochfordi*, a compact-growing variety, finds some favour as a pot plant. This is identical with *A. grande*. There are many slight varia-

tions of the cuneatum type, and in selecting plants for spores it is essential to choose those of the best habit. All the Adiantums used for market work should be grown well exposed to the light and confined to rather small pots. It is only when the pots are full of roots that they make the firm, hard fronds so necessary for decoration either when cut or as pot plants. Of the Aspleniums the most popular is *A. bifforme*. There are several slight variations of this. One I had from Messrs. Backhouse and Son some years ago under the name of *divaricatum* is the best form I have met with, and most growers have this under the name of *bifforme*. The true type of *A. bulbiferum* is a useful Fern, but rather slow. *A. laxum pumilum* is another popular variety, but it is not quite so prolific in young bulbils, and consequently does not find its way to market in such large quantities. It is, however, worth looking after, as it will generally command a higher price than *A. bifforme*. *A. bulbiferum* var. *Hilli* is a new variety with narrow and more erect fronds than the type, and seems likely to make a useful Fern, more especially for small pots. *Lonarias* are not so popular as formerly, yet *L. gibba* when well grown finds some favour, more particularly for provincial trade. Of *L. ciliata* the normal form was of little use, but the variety *major*, which is of more vigorous growth and has fronds altogether of better substance, makes even a better plant than *gibba*. Seedlings are a little inclined to vary, as far as I have seen, but with careful selection I think it might even yet be improved upon. Within the last few years *Nephrolepis* have come much to the front. The most popular is *N. exaltata*, which makes such a grand basket Fern. It also makes a fine pot plant, and no Fern now finds a more ready sale. The best form is that which is grown in America as *N. bostonensis*. *N. davallioides fureans*, *N. plumosa*, and *N. tuberosa* may all be included as useful market varieties. There is not a large demand for *Davallias* as market plants, but they deserve more attention, especially those of

the *dissecta* type. When raised from spores and grown on freely they make very pretty plants and stand well. All of the *bullata*, *fijiensis*, and *cariensis* types vary when raised from spores, but they make much more compact plants than those propagated by division, and are very pretty in quite a small state. They should not be given too much heat, but should have plenty of light, with a fairly moist atmosphere.

Cyrtomium falcatum ranks as one of our first market Ferns and is grown in very large quantities. Although nearly hardy it may be grown in heat, but there must be plenty of moisture, or thrips will be troublesome. Potted in good loam, with a little manure added, it grows freely and makes fronds of good substance. There are several varieties, but it is rarely met with except under the old name. The variety *laeinatum* or *Fensomi* is the best. The *Pterises* are the most important of all for market work. Though confined to comparatively few species, the varieties are very numerous, especially of the *cretica* and *serrulata* types. Of the former, *major* is perhaps more in demand than any other variety at the present time. The variety *Ouvardi* has long been considered the best form of this, but I have lately seen a variety named *Drinkwateri* which seems likely to supersede it, having broader pinnae, the fronds having great substance. In a large batch raised from spores there seems little variation. Of the crested varieties of *cretica*, *Wimsetti* is certainly one of the best. It is remarkable how true this comes from spores. A good selection of the ordinary *cretica cristata* also finds much favour, while *nobilis* seems to have dropped behind during the last year or two. The ordinary type of *P. serrulata* is still in demand, but the broad forms of *cretica* have to some extent taken its place. Several crested varieties of *serrulata* are also extensively grown, the true form of *cristata compacta*, as sent out some years ago, being one of the best. To keep a good stock it requires care in selecting the spores. The heavy tasselled varieties should

be avoided. *P. tremula* takes a front rank among market Ferns, and in this again, though not usually distinguished by names, there are several distinct varieties, those with the broad pinnules and nearly triangular fronds being generally preferred. In growing on this useful Fern, if three or four young plants are potted together, one will generally take the lead, but the weaker ones help to furnish the base with smaller fronds, while when grown singly the plants are apt to be rather thin at the base. The pretty crested variety *Smithiana* has not proved a valuable market plant, being too brittle to stand the rough usage that market plants usually get. *P. argyrea*, though not grown to the same extent as any of the above, finds some favour. It is often grown in too high a temperature, and is very tender besides running up tall, but where grown cool and two or three plants potted together it is very useful. Out of the great number of species and varieties of *Polypodium* there is only one which may be considered a useful market Fern. This is *P. aureum*. The pale glaucous green gives a nice contrast to other Ferns, and it is one of the most vigorous growers we have. In very cold weather the fronds turn black if exposed, but otherwise it stands well and will last in a room unless the temperature goes down nearly to freezing point.

Of Ferns which are not so extensively grown, though very useful, I may mention *Doryopteris palmata*, *Osmunda palustris*, *Lastrea patens*, *L. aristata variegata*, and others, but those who wish to succeed should confine themselves chiefly to the standard varieties, and be very careful not to go in for large batches of those not in demand. A.

KITCHEN GARDEN.

GARDEN TURNIPS.

The past season has been one of the worst on record for the production of sweet, juicy Turnips, for since the showery month of May very little rain has fallen in this district, and the weather at times has been unusually hot, which was anything but favourable to the production of delicately flavoured roots. It is well to note in such weather how the different varieties have stood the drought and the length of time they were fit for the table. I will take the early ones first. Up to the end of April only 4.72 inches of rain had fallen during the year, so by that time the soil had got fairly dry, vegetation had not made much headway, most things being backward for the time of year. In May we had 3.45 inches of rain, which thoroughly moistened the soil, so that growth was more rapid. Early Milan, which is a favourite with most people, did fairly well, but the roots are flat and soon go stringy, being only in first-class condition for a few days when the weather is dry. Cardinal is a red variety of this type, and soon goes tough. White Milan is another, and the same may be said of Scarlet and Yellow Perfection. The two varieties that find most favour here for early sowing are Snowball and Early Stone. The former, if a true stock be procured, makes handsome roots with a good depth of flesh, which is of most delicate flavour. This also remains in good condition for a longer period than any of those previously named. The Early White Stone is an excellent variety for spring and summer use, the roots of good shape and well flavoured, being quick in growth and retaining their flavour for some time. Amongst the mid-season kinds I may mention Carter's Purple-

top Strap-leaf. The shape is good, it grows quickly, and the flavour is excellent while it lasts, but, unfortunately, in hot weather it soon goes strong, necessitating frequent sowing. Carter's Golden Rose—why so named I do not know, as with me there was no rose colour about it—is a beautiful yellow-fleshed variety of handsome globe shape, the upper portion of the skin of a brownish colour. This remains in good condition for a long time, and those who prefer yellow-fleshed varieties will find this a good one. Green-top Stone is also one that should not be lost sight of, as it is hardy and resists the frost well. In Criterion, a late variety, the skin on the upper portion is pink, and the roots tankard-shaped. It resists the dry weather well, the roots penetrating the soil to a greater depth. Of all the varieties that I have yet grown for late use Red Globe is the best. The roots are handsome in shape, flesh very delicate, while for both growth and hardness it will stand the test with any other variety in commerce. Those who procure a true stock of this should make two autumn sowings, one at the end of July and the other about the middle of August.

Three things are essential for the production of first-class Turnips. First, the soil must be rich without the addition of any fresh manure near the surface; second, ample room must be allowed for the roots to develop, for when allowed to stand too close together more foliage than roots is made; thirdly, they must never be allowed to suffer from want of moisture, particularly when small, for when this happens the roots are sure to be tough and stringy. With care and attention, good sweet roots may be had from the open ground from the latter end of May or early in June till March the following year. It is, however, advisable to make only small sowings at short intervals between March and July, after which date a greater breadth may be sown. As the weather becomes cooler the roots do not so soon get tough. It is always well to make a sowing towards the end of August, for if the winter be mild these late sowings will grow through the winter and be found very serviceable in early spring. H. C. PRINSEP.

Globe-shaped Beet.—When looking round the Royal Horticultural Gardens a few weeks back I noticed a fine strain of the above Beet growing on one of the open quarters. It certainly is the best shaped type of Globe Beet that I have ever seen, and is a wonderful improvement on the older and flatter kinds which were generally grown a few years ago. Another thing which struck me was the uniform growth both of the tops and the roots, and not a rogue was to be seen amongst them. On testing one of the latter, the colour was found to be dark and rich-looking, and had every appearance of proving to be a first-class table Beet when cooked. Anyone after seeing this fine type of Beetroot would not care to again grow the flatter-shaped Egyptian and other similar strains, so infinitely superior is it to them. —A. W.

Borecole, Arctic Green Curled.—With many growers this year the Kales are not a success, as, unless planted before the heat and drought were so great, they suffered badly. The broad-leaved Kales, such as Asparagus and similar kinds, are not at all good in soils very light and porous; indeed, in the southern parts of the country there is a great want of good winter Kales, such kinds as Ragged Jack and Cottager's Kale having suffered much from disease. The newer forms of Arctic Kales, of which there are two distinct kinds, the purple and green, are specially good this season. These plants stand drought grandly. Mine were planted on land cleared of early Strawberries. The ground was not dug, merely hoed

over, and rather deep drills drawn. The plants now present a beautiful appearance, and will give a lot of cutting material for some months. I like the green variety best, but the purple is quite as good.—G. W.

Feeding Rhubarb.—Those who force Rhubarb, well know the value of giving food, and there is no time better than the present, as the plant being free of leafage may be given food in the shape of a liberal top-dressing of decayed manure. Not only is food well repaid in the quantity and quality of the produce the next season, but the produce is earlier if the winter is severe, as if the manure is given early in the autumn it is pulverised and acts as a protector in the spring. I find it an excellent plan to give Rhubarb any spare material in the shape of a mulch. If manure is scarce, old leaf-soil mixed with a fertiliser makes a good food, and much finer growths and better colour will be obtained. A greater weight of produce is obtained if new quarters are given every three or five years. I sow seed for this purpose, but equally good results may be had by root-division.—S. B.

Artichokes flowering.—These flower only in late seasons, or in those in which there has been a somewhat prolonged period of bright weather. These conditions obtained in a marked degree this year. Artichokes flowered more freely than usual, and, used as cut flowers for room decoration, they have been very striking and, to some visitors, of much interest. There is in these a more decided depth of colour than in any of the annual Sunflowers, which they so closely resemble, and this is heightened by the black scaly calyx of the unopened buds. Unlike Sunflowers, too, I found that, instead of withering in a few days, they improved in the house from the development of the unopened buds. They take up a deal of water through the stems, which made it necessary to arrange them in large vases. Given this they lasted well a week, and were fresher than Sunflowers were after two or three days.—W. S.

Edible fungi.—Among the edible fungi available at this season of the year I should be inclined to give preference to the tall or cylindrical *Agaricus*. Several modern garden books do not notice it at all. I do not know by what particular name it is known among the Agarici other than as I have described it. Perhaps some reader of THE GARDEN may be able to give it. It is generally to be found in moist, shady spots, and if the shade is so that the sun's rays only at any time partially penetrate and the soil is good, then this fungus is seen at its best, and half a dozen specimens will furnish an excellent and appetising meal. I have it every morning all the time it is procurable. It is much more digestible than the common Mushroom, and many unable to eat the latter will find no ill effects from the tall variety. Popular prejudice, however, runs strong, and those who partake are regarded as doing so at the risk of their lives, with the result that in districts where this *Agaricus* is fairly plentiful, those who like it have little difficulty in always obtaining a supply. I write fairly plentiful, never as yet having lived in a district where it was found in any great quantity. A very considerable amount of liquid comes from it in the cooking, leading one to infer that if grown largely it would be very useful in furnishing material for catsup.—E. BURRELL.

Winter Lettuces.—A novel method of growing Lettuces for winter was brought to my notice last year, and as the results obtained surpassed anything I had ever before seen in the way of winter Lettuces, the means of obtaining them may be of interest. Seed was sown in the usual way early in the autumn, the plants when large enough were pricked out into cold frames, using as soil nothing but pure leaf-mould, in which they made rapid progress and hearted in beautifully, keeping up a full supply of well-blanching hearts all through the winter and early spring months. These Lettuces found a ready sale at 4s. per dozen and were well worth the price obtained.

The treatment given was to exclude all air from the time the hearts commenced to form, the result being tender and succulent growth throughout. All the care they had was to protect them from frost by matting up the frames when necessary. I have no doubt that the variety of Lettuce grown had much to do with the success. Unfortunately, I cannot say precisely what it was, but it appeared to be intermediate between the Cos and Cabbage varieties, the leaves pale green throughout, and it much resembled a variety which I have seen exhibited under the name of Paresseuse. A few plants which I obtained from the grower and potted up have seeded, and I hope to be able to try it another season. The grower was, I believe, for some time in market gardens in the neighbourhood of Paris, where he appears to have made a special study of the cultivation of salads, and he is now adopting, very successfully, similar methods at home. He saves his own seed of this particular variety of Lettuce and, to get it, grows his stock plants in pots where they can be protected from rain, as he finds those grown in the open very uncertain in the matter of seed production.—J. C. T.

GROWING ASPARAGUS.

PLEASE give me the fullest instructions for treatment of Asparagus beds for the year. Is fish manure a safe thing to use?—J. ARDEN, *Fulbrook, Burton-under-Nedwood.*

* * As regards the treatment of Asparagus beds for a year, much depends on whether the beds are old or young, the soil light or heavy, and the strength of the plants. It will not answer to give strong fertilisers in the shape of nitrates or even fish manure and guano to weak seedlings. A well-made bed will need little food for the first two or three seasons if the plants are obtained from seed. Much better results will follow irrigation if the soil be light. Many often make a mistake in heaping large quantities of manure on the beds at this season of the year. I do not advise it even with the lightest soil, as when the plants are at rest they are unable to absorb the food given. As much depends on how the beds are made, it will not be out of place to refer to the same. The best plants I have ever seen in this country were grown on the flat in rows. The land was deeply dug and plenty of manure used. The plants never received any attention from October to March, but during growth they were well fed, and a system of irrigation could be effectually carried out in dry seasons. Sowing is done in the spring. The seedlings will not need much attention other than thinning and cleansing. Thinning is an important detail, as unless the work is done thoroughly there will be a crowded plant. I have seen Asparagus sown like Mustard and Cress, and when finally thinned there have been a dozen plants where one would have sufficed. The culture of the plant the second year is simple. It may be necessary to thin again here and there if the plants are doing well, and a light top-dressing of manure may be given between the rows. This is more in the way of a mulch to encourage surface roots and retain moisture than as food. The third year cutting will commence, but not much, and the same remarks hold good as regards mulching. Liquid manure, if it can be given, is the best food. When seedlings are purchased or grown for planting, they may be one or two years old. For such plants the soil is well prepared. The first year no food is necessary, but after planting, if light manure of any kind can be given as a mulch it is most beneficial. In light soils the mulch is a necessity with young plants.

If the kind of soil had been stated this would have helped considerably. Feed from May to September, as this is the time the plants benefit by the food given. In light soils a dressing of sulphate of potash given at the rate of 2 cwt. or even 3 cwt. per acre is an excellent fertiliser, and a dressing in the early autumn will be well repaid. Sulphate of potash is an excellent food to mix with other manures

such as guano and fish manure. Guano by itself is an excellent fertiliser. This and fish manure are best applied in showery weather, as the moisture washes the food to the roots. There is no better food for Asparagus than fish manure, but I prefer to mix it with potash or sulphate of lime. If used, say, from May to the end of August, you cannot have a safer manure, but in dry weather near dwellings it is offensive. To remedy this I mix it with soot or lime and rake it into the surface. Fish manure may be used at the rate of 3 cwt. to 5 cwt. per acre, or 1 oz. to 2 oz. per square yard. A dressing of fish manure given once a month will suffice—I mean during the growing season—and in dry weather if watered in it is an excellent food. At this season of the year I dress heavy soil with the following: Fish manure, one half; road-scrappings and burnt soil or refuse the other half, with a liberal quantity of bone-meal. In the summer, too, such a mixture or liquid manure may be given freely. In heavy soils, salt must be used very sparingly. No one can go far wrong in irrigating freely, as Asparagus delights in moisture and frequent supplies of food.—S. M.

ORCHIDS.

PLEUROTHALLIS.

ALTHOUGH a very large number of species are included in this genus, but few of these are grown in gardens, or, indeed, known. They have been introduced and passed in and out of cultivation time after time, but the average Orchid grower knows nothing of them. Very few are included even in the best collections, and one may enter a great many places without seeing a single plant. It is a pity that some at least are not included in present-day collections, for the flowers of many of the species possess in a marked degree the delicate beauty and quaintness of form that have all along made the family so popular. As an instance take the Gnat Orchid (*P. Barberiana*). I have had this delightful little plant in baskets suspended from the roof in the cool house with spikes about 6 inches long, but quite invisible at a little distance, and if the basket containing the plant was jarred or shaken, the flowers resembled nothing more than a cloud of gnats hovering about the basket. If the basket is set in a slight draught, the dancing motion of the flowers is kept up, and the illusion is complete.

Many other interesting kinds might be named, but not much good would be done by describing them, for in the first place they are but little known, and, again, a description of such plants is always unsatisfactory, and conveys no real conception of what the flowers are really like. As to their culture, they may be grown by anyone who will give a little attention to their needs, and if interested in this class of plants no one will regret taking up their culture. The majority are purely alpine species, occurring at altitudes varying from 10,000 feet to 12,000 or more feet, so, unless in exceptional cases, all may be grown in a cool house, such as is usually advised for *Masdevallias* of the showy-flowered section and *Odontoglossums*. Being of a dwarf, tufted habit, anything in the way of atmospheric checks must be carefully avoided, for these are sure to bring insects in their train, and an attack of thrips to such tiny plants means destruction if immediate means are not taken to clear them off. A mistake often made with cool Orchids of this class is throwing the house wide open in the middle of a summer day. Nothing is gained by it; the atmosphere loses all the moisture and gets as hot as possible. Ventilate freely in early morning and again in the evening, leaving a

good amount of bottom air on all night. This is far better, for the atmosphere is always fresh, and then to keep the moisture in in the middle of the day, take most of the air off and shade as heavily as possible. Of course, damping of the stages, floor, and even the plants themselves must be freely indulged in, for with the temperature outside standing at about 30° higher than we want inside, no amount of atmospheric moisture can do any harm.

As to the winter treatment, just the opposite conditions prevail. In their mountain homes day and night are more nearly equal through the year, owing to the proximity of the equator, and consequently under cultivation the plants miss the long daylight, pining in our dark, dull winters for the long sunny, though cool days of their native haunts. The best we can do is to keep the glass roof clean inside and out, allow as much air as possible without unduly lowering the temperature and water the plants with care, according to their lessened needs. At no time must anything like drying off be practised, only a reduced supply when the conditions outside and the small amount of growth going on render this necessary. The compost required for *Pleurothallis* is very much like that *Masdevallias* and other alpine Orchids thrive in, a thin layer of Sphagnum Moss and peat over efficient drainage, with plenty of finely-broken particles of crocks and charcoal for the roots to take hold of and to ensure aeration, suiting them well. Always repot the plants before they get into really bad condition, or they may be checked badly and take a long time to get over the disturbance. Rather small pots are usually advisable, as the habit is mostly tufted, and in the majority of cases the roots are small and not able to occupy a large body of compost. If there is a margin of half an inch in the smaller and an inch in the larger pots around the outside of the plants, this will in most cases be ample for their needs. H. R.

Cypripedium Regina.—This hybrid is extremely rare—unique, in fact, there being only one plant in existence. Its parents are *C. Fairieanum* and *C. Leeatum*, and it is so clearly intermediate between them, that its parentage may be guessed at a glance. The drooping petals, which show the *Fairieanum* influence, are whitish, shaded with green and lined with shades of brown. The staminate has a deep apple-green area, which is repeated at the base of the dorsal sepal and in feathery veinings higher up. The upper part and the spotting are more like *C. Leeatum*. The labellum is greenish and brown, the open part of the throat being spotted with reddish brown. It was raised by Mr. Seden in Messrs. Veitch and Sons' nursery.

Cypripedium Arthurianum.—The influence of the seed parent of this hybrid—*C. insigne*—is so plainly apparent, that one is somewhat apt to look upon it as a variety of that species, though a glance at the petals shows the pollen parent to be *C. Fairieanum*. The colour and the shape otherwise are almost exactly those of *C. insigne*, the spotting on the sepal and the colour of the labellum all being similar. It is a beautiful and distinct plant notwithstanding, and a fine specimen of it carrying seven flowers I noted recently in the Cambridge Lodge collection. It is not often so fine a plant is seen, for not only is it flowering freely, but it is also in the best of health. *C. Arthurianum* is not a particularly strong grower, yet it is free and not difficult to keep in health if healthy when received. *C. Arthurianum* first flowered in 1874.—H. R.

Vanda Sanderiana.—I have previously noted the desirability of cultivating this species in baskets so that it may be suspended from the roof, thereby enabling it to obtain the maxi-

mum amount of light. Especially during the autumn months, when the flowers are expanding, is this advisable: it adds substance to the flowers and intensifies the colours. It is also a safeguard against the ravages of cockroaches. These troublesome insects are particularly fond of the flowers and roots of this species, and every endeavour must be made to prevent their reaching the plants. This species grows and flowers freely suspended from the roof of the East India house in Mr. Cobb's collection at Tunbridge Wells. I recently saw a plant there with five spikes and fifty-one expanded flowers. Two other large plants gave promise for a fine succession of bloom.—H. J. C.

Lælia monophylla.—This dwarf-growing Lælia does not receive the attention it deserves. In the late summer and autumn months, when flowers are scarce, it is most useful. It will grow and flower freely even under the unfavourable atmospheric conditions of London. It does best in the cool house through the warm summer months, and during the cooler months of the year it is best removed to the cool intermediate house, where the temperature does not fall below 50° at night. It should be grown in baskets or shallow pans suspended from the roof. The compost required is good fibrous peat and Sphagnum Moss in about equal proportions. To this may be added a liberal sprinkling of finely broken crocks. It requires an abundant supply of water during the growing season, with only sufficient to keep the growths in plump condition during the long resting season, which usually lasts from October to June. The flowers are rich orange-scarlet, each upwards of an inch in diameter, the growths from 8 inches to 10 inches long. It is an interesting species, being the only Lælia that is not found on the American continent. It is a native of St. Andrew's Mountain, in Jamaica, and first flowered at Kew in 1882. It is, therefore, practically of recent introduction. The species has never been plentiful, and I have no doubt it is to a great extent owing to its not being better known that it is so seldom met with in Orchid collections. I recently noted a finely flowered plant in one of the cool houses at Dulcote, Tunbridge Wells, where Mr. Walter Cobb has now removed his collection.—H. J. C.

MASDEVALLIA TOVARENSIS.

FEW white-flowering Orchids are more useful for cutting than this Masdevallia, a proof of its great utility lying in the fact that many florists with a demand for choice blooms grow it in large quantities. The flowers are of the purest white, without a spot of any other tint, and very freely produced when the plants are strong and healthy. As a rule, if the flowers are wanted in quantity the spikes are cut entire, but if the individual flowers are taken off and wired the spikes push others in subsequent years. I have heard it said that this makes no difference to the amount of bloom produced, that the flowers push fresh stems more freely when the older ones are taken out, but I can hardly credit this, and wherever possible, I should prefer to leave the spikes intact. During the growing season and all through the summer and early autumn the plants can hardly be kept too cool. They should be grown in a house well shaded from the rays of the sun, and overhead as well as atmospheric and root moisture must be very abundant. Any slackening of either is sure to result in a check to the plants, and may possibly bring on a bad attack of thrips, one of the worst insect enemies to cool Orchids. When the flowers are forming, it may be necessary to give a little more warmth, and when fully expanded a drier atmosphere is very necessary, or the fragile delicate beauty of the blossoms is soon spoilt. The winter temperature ought not to fall much below 50°; this is quite safe, but no less should be the rule, though a degree or two less on very cold nights may be preferable to forcing the fire-heat unduly. Regarding the compost, a thin ayer of

Sphagnum Moss and peat over good drainage is all that is required, and I like to see the former growing freely about the base of the stems, this keeping them cool and moist and being a good index to the state of the roots for moisture. Repotting should take place about once in two or three years, this being quite often enough if properly done. While not disturbing the roots more than is absolutely necessary, be careful that nothing in the way of old sour compost is left behind, as this will soon spread to the healthy part and fine down the whole. This class of plant is better not too much elevated; the base of the stems keeps moister and it is easier to water them when only slightly raised above the rim. I always use the syringe for moistening this class of plant, forcing the water through a fine rose being much preferable to using an ordinary spouted can. Should thrips at any time put in appearance, lose no time before vaporising the house, and if time can be spared the plants should be carefully sponged afterwards. This latter is the only course likely to succeed in getting rid of the white, soft scale that frequently attacks this species. *M. tovarensis*, as its name implies, is a native of Tovar, in New Grenada, where it was discovered in 1849. It was for a very long time rare in cultivation, but about twenty years ago it was reintroduced in quantity by Messrs. Hugh Low and Co., since when it has been plentiful.

ODONTOGLOSSUM SCHROEDERIANUM.

It is a pity that De B. Crawshaw did not give readers of THE GARDEN fuller details of the history of the two plants which have certainly existed under the name of *Odontoglossum Schroederianum*. It is very questionable, judging from the report in THE GARDEN of the first plant exhibited, if there are not three under that name. Particulars as to how these complications arose can be easily traced. Reichenbach in *Gardeners' Chronicle*, May 27, 1882, p. 700, gives the original description. This description appeared in Messrs. Veitch's "Manual of Orchidaceous Plants," with an additional foot-note to the effect that they had not seen the plant. The Royal Horticultural Society's "List of Certificated Plants" gives the information that *Odontoglossum Schroederianum* has been twice awarded a first-class certificate, the plant on each occasion coming from the collection of Baron Schroeder. The first time was on January 13, 1885. This is described in THE GARDEN report of that meeting as being an *Odontoglossum crispum* of the *O. c. guttatum* section. The second plant, exhibited on September 13, 1887, is described in THE GARDEN as belonging to the *Odontoglossum love* section. Judging from other reports of the meeting, there can be little doubt that the plant was none other than *Miltonia Schroederiana*. *Miltonia Schroederiana* was figured as *Odontoglossum* in Williams' "Orchid Album," vol. ix., p. 382, and in Sanders' "Reichenbachia," vol. ii., p. 96. Though Veitch's Manual points out the confusion that existed when referring to *Miltonia Schroederiana*, the author of the above work does not further clear up the matter.

The first *Odontoglossum Schroederianum* is described by Reichenbach as being a supposed hybrid between *O. tripudians* and *O. Pescatorei*. Surely this could not have been the variety exhibited by Baron Schroeder on January 13, 1885, which THE GARDEN report gives as being an *O. crispum* of the *O. c. guttatum* section. No one could possibly describe a hybrid between the above-named species as a finely spotted *O. crispum*. The second plant certificated (which is well to note, was only a little over two years after) was undoubtedly what I referred to as *Miltonia Schroederiana*.

Here is where the muddling of the two species occurred. What excuse can the exhibitor attempt to set up for showing two such widely different plants and getting them certificated under the same name? I have no doubt the blame lies with the committee of the Royal Horticultural Society in awarding certificates under

the above conditions. The further facts that plants were afterwards figured, distributed by the trade, and up to the present day known in many private gardens under the name of *Odontoglossum*, led me to use that name in parenthesis after the word *Miltonia*. I think with this explanation it will be found that I had ample grounds for the use of the two names in the manner I did on p. 297. STELIS.

Cattleya labiata autumnalis.—The earliest flowers of this popular Cattleya opened the first week in October, while some of the later *C. Gaskelliana* were quite fresh and good. These are two of the most useful species, and the old *labiata* especially so. The colours of the blossoms are as variable as those of any other in the section, and it is an easily-grown, free-flowering kind. It may be grown in the usual Cattleya house temperature in a rough, open compost such as all these kinds delight in. If possible, the plants should be given new compost just after the flowers fade, as there is often a flush of young roots at that time.

Saccolabium curvifolium.—A spike of this pretty Orchid comes from "C. C." for a name. It is a useful little species, flowering at various times of the year, the racemes being erect, the blooms a bright red, though this varies considerably in different plants. The plant comes from high latitudes in the Himalayas, and under cultivation thrives in small baskets or pans suspended from the roof for choice. Plenty of air and all the sunlight possible without injuring the foliage may be allowed, and under these circumstances the temperature may read fairly high.

Promenæa stapelioides.—The flowers of this species are very singular in colouring, being on the sepals and petals a pale yellowish green, with markings of brownish purple. The lip has a purple lobe in the centre, the side lobes being somewhat lighter than the other segments but similarly spotted. It is sometimes described as a *Zygopetalum*, but is more generally met with under the above name. It thrives well in small pans suspended from the roof of an intermediate house and requires careful shading. It is a native of the Organ mountains and other parts of Brazil, and was introduced in 1830.

Odontoglossum elegans.—The better forms of this pretty *Odontoglossum* are worth taking every care of, for they are easily grown and very free-flowering. The origin of the plant is doubtful; indeed, it is very variable, and there can be little doubt that any suggestions as to its parentage can only refer to certain individual plants. The usually accepted theory is that it is the result of a wild hybrid between *O. cirrhosum* and *O. cristatum*, but there are signs of several other species in some of the forms labelled *elegans*. Whatever its origin, it is a useful and beautiful plant, thriving well in the coolest house and throwing up fine many-flowered spikes at various times of the year.

Dendrobium taurinum.—Few Orchids that are so strong as this species in their native habitat give so much trouble under cultivation. Collectors tell us that the stems of this species are considerably taller than a man, and that the racemes of flower produced are very large and vigorous, but such results are rare or rather unknown under cultivation. If we get stems a yard high and flower-spikes a foot long we are content, and it takes a deal of care to keep plants healthy and strong even at this. The species delights in ample heat and moisture and a light sunny position not far from the roof-glass. The baskets or pots should be of medium size only, and the usual compost of peat and Moss suits it well. The name *taurinum* was given it by Dr. Lindley on account of a resemblance to the forehead and horns of a bull in the twisted erect sepals and lip of the flower. The colour of the flowers is a greenish white, with lines of purple. It is an old inhabitant of our houses, having been discovered by Cuming in the Philippine Islands more than half a century ago and sent by him to Messrs. Loddiges.

FLOWER GARDEN.

GUNNERA MANICATA IN THE NORTH.

I HAVE sent some photos, taken in 1896 and 1897, to let you see the growth *Gunnera manicata* makes in one year. This year the largest leaf measures 7 feet 7 inches, and the plant is 7½ feet high, 17½ feet through, and 50 feet in circumference. It is planted in a garden and is not near water. All the protection I give it in winter is its own leaves cut off and reversed over the plant.

FANNY A. FIRIE.

Countesswells House, Aberdeen.

Carnations.—An inspection of Carnation layers made at different intervals along the border shows that, on the whole, they are extremely well rooted, and that despite the exceptionally dry time right away from layering until the beginning of October. This state of things, decidedly better

stated. The border on which the bulk of the layers will be planted is rather heavy, and I have, therefore, worked in a liberal dose of peat moss manure, arranging it evenly in the trenches and at such a depth that the roots of the plants will come into immediate contact with it. New varieties of whose hardiness I have had no personal experience always remain the first winter around the parent plants.—E. BURKELL.

Carpet plants for bulbs.—Where bulbs are established on hardy plant borders or have been planted this year it will be advisable to consider how best to carpet the ground, if this is not already done, so that bare patches are not in evidence when the flower and foliage of the bulbs are at an end. I have no liking for bulbs in such positions; even in small gardens other places can be found for them either in occasional corners in shrubberies, on bits of grass that are not clean shaven by the machine or scythe, or on borders mainly devoted to small conifers and shrubs both deciduous and evergreen, with which they asso-

the position of the grubs, if one was applied of sufficient strength to kill the grubs, the plants would also suffer from its effects, so that at any rate the remedy would be as bad as the disease. The only way is to examine the roots of any plant that you suspect to be attacked and pick out the grubs. The parent weevils feed on the leaves of Vines and other plants at night, being seldom, if ever, seen in the daytime unless disturbed, as they then hide themselves most carefully. If you for any reason imagine that your Vines or other plants are infested by these weevils, before it is dark you should lay white sheets or cloths under them, and then later on throw a bright light on the leaves. This will probably cause the beetles to fall; if it does not, give the plants a jarring shake and search them well. They may be trapped by tying little bundles of hay or dry Moss on to the stems, as they will hide in them.—G. S. S.

Hardiness of *Dracæna australis*.—Although it is not unusual to see *Dracenas* or *Cordylines* growing in the open air along the south coast in Cornwall, the Scilly Isles, and the milder parts of Ireland, people rarely trust them unprotected to the rigours of winter in more northerly situations. The species under notice, however, is one which seems capable of standing a good deal of frost—quite up to 20°—and this is a strong recommendation for a plant which will give a garden a sub-tropical aspect in the depth of winter. Quite recently I saw two nice specimens between 5 feet and 6 feet high planted out on the lawn at Mr. Worsley's, Mandeville House, Isleworth. These plants were originally obtained as suckers from a plant about 20 feet high, which had stood out in the north of England for many years, but eventually had its top and stem killed by 25° of frost. Mr. Worsley, who takes a keen delight in acclimatising all kinds of plants, is of opinion that *Dracæna australis* is practically quite hardy in all places south of the Tweed, although it would probably be advisable in severe winters to give a little protection to fine specimens.—JOHN WEATHERS.

Gunnera manicata in an Aberdeenshire garden. From a photograph sent by Miss F. Pirie, Countesswells, Aberdeen.

than I anticipated, is doubtless owing to the fact that they are on a north-west border and so screened from very hot sun, and also that in the early stage they were thoroughly well attended to in the matter of water and never allowed to get dry. I have debated whether to shift them now from their present quarters to the position they are to occupy another season or to wait until early spring, and I have decided on the latter course, except in cases where clumps are required to complete new planting arrangements on herbaceous borders. For the latter purpose I have picked out Countess of Paris, Raby, White Clove, The Pasha, and Murillo as representing the sturdy, free-flowering section with blooms borne on short, stout stalks. Hayes' Scarlet, King Arthur, and Mrs. Maeræ are all superior to Murillo from a purely flower standpoint, but they are much longer in the stem, requiring considerable attention in the way of staking and tying. For the same reason preference is given to White Clove over Mrs. Eric Hambro' for positions above

ciate remarkably well. Where, however, bulbs are required on the hardy plant borders, the carpet plants may be added at the present time, among the best things for the purpose being the alpine Phloxes, Aubrietias in variety, Tufted Pansy Violetta and *Cerastium tomentosum*. Small plants of all these from cuttings obtained in their different seasons will now be available, and if the soil is pricked up, taking care not to disturb the bulbs, the tiny plants can be inserted sufficiently close together so that at once they fairly cover the ground.—E. BURKELL.

Primulas attacked by larvæ.—My Primulas are being ravaged by larvæ, which eat through the stem just below the ground. I send you one of the creatures, and shall be very much obliged if you will tell me what it is and what steps we ought to take.—G. TOMKINSON.

* * * The larvæ attacking your Primulas are the grubs of the black vine weevil (*Otiorrhynchus sulcatus*). I am afraid that it is of no use trying to destroy this insect with an insecticide, as from

CACTUS DAHLIAS.

My cultivation of Cactus Dahlias began with the arrival of Juarcz, and as the breaks from it became distinct, so I added them to my collection until it became fairly representative, and in this paper I propose to give my experience of their qualities, with suggestions as to treatment, which may be new to a few readers.

Whites.—If Mrs. Peart be grown from old tubers in rich moist soil, well helped during flowering and shaded from the sun, a large number of perfect flowers will result, and it still holds with me premier place as a show flower and does not require much disbudding. If Mrs. F. Fell be treated in the same manner (except that it is not needful to grow it from old tubers, as it gives fine flowers from spring-raised stock) and severely disbudded and tiffany screened, very exquisite flowers will result, and late in the season their form may be perfect. So far with me Keynes' White can only be described as a pretty little flower, very free and white, but lacking size and substance, and on fully expanding shows large yellow centre. This is the fault of Mrs. Peart not infrequently, never of Mrs. F. Fell.

Yellows.—Lady Penzance so far has no competitor.

Dark velvet crimson.—Matchless still retains its place in the first rank, and never goes wrong.

Crisp.—Crisp leaves nothing to be desired, and can hold its own as a bedding Dahlia or for single specimens in borders grown as a standard; quite one of the best.

Orange-vermillion.—Starfish with its perfect form is an ideal flower, and should be freely grown and disbudded.

Pure orange. Francis Humphreys alone represents this very telling colour; the flower is coarse, but until we can get an orange Starfish we may

rest content. It is a fine variety for standards, and does not require disbudding.

Mauro.—Beatrice has given me some beautiful flowers without disbudding, and forms a fine standard, but Island Queen, well shaded with tiffany, will next year take premier place.

Purple has only Earl of Pembroke, which requires very heavy feeding and does not require disbudding.

Terra-cotta.—Mrs. Wilson Noble has a lovely form and exquisite Pistachio nut colour. Countess of Lonsdale is supposed to be an improvement; but with rich culture, heavy disbudding, and generally skilful management, Mrs. W. Noble can hold its own.

Scarlet.—Gloriosa, which does not require disbudding, is even yet premier, although in Captain Broad we have a fine second. The charm of Gloriosa is its noble habit, and when grown as a specimen standard in the border it is a grand addition to the autumn resources of the garden. I have here to-day (October 22) several plants, one of which I measured for the purpose of this paper, there being little difference between them: Height 8 feet 7 inches, diameter through head 6 feet, carrying forty-six fine open blooms, innumerable buds, and fine foliage—a veritable tree. The value of these grand plants for long borders, grown and trained on twig supports, cannot be over-estimated. There need be nothing stiff or formal if attention be paid to the suggestions given further on. Supports are necessary, because at so high an elevation as 8 feet there is less protection, and wind is a serious enemy to the Dahlia.

Red.—Fusilier is a fine variety, of good form, free flowering, and nice in colour. It also can bear heavy disbudding and disbranching; its blooms are then very constant in form. I have not seen Lucius, but as it has received the premier prize for 1898 it must be accepted as a fine addition; so also Clown, among the fancies, a white-tipped red, and Fantasy, of an arachnoid shape, is very charming, but in Arachne we have reached nearly to perfection in form, colour, and habit. One of its decorative charms is its sporting, although very trying for show purposes. I have now plants laden with flowers, each carrying three or more varieties of bloom, so distinct in colour that they may be shown under separate names. The form of Arachne is very fetching, and when properly supported, as I shall show later, it is the most beautiful single specimen grown. Of the more delicate shades in combination, Bridesmaid is a fitting specimen, a pale primrose, mauve tinted, very beautiful form, and reliable all through the season.

Rose.—Quite the best rose in colour is a new flower, exhibited by Dickson, Chester—Mrs. Dickson. It is somewhat like Bertha Mawley without its blue tinge, and will improve in petal. It is a little flat at present. With Leonora, a finely-shaped flower of a peculiar crushed strawberry tint, I may close my list, only adding that in omitting a description of such as Sirdar, which displaces Harry Stredwick, I admit its beauty, and include it in my list of the best twenty-four. Necessarily the fashions and types change; therefore the old are displaced by the new, not that they are decoratively more valuable, but from a florist's point more desirable. In selecting three whites, I am guided by the knowledge of their fickleness. No skill can ensure perfect show flowers at a given time: therefore to meet all contingencies, grow three varieties, and plenty of them.

The cultivation of Cactus Dahlias is not difficult, the points to determine being—

1. Which varieties flower best from old tubers, which from pot tubers, and which from spring-raised cuttings?
2. How much, if any, disbudding and thinning is necessary for each variety?
3. How to protect and shade such as require it?
4. The best way to grow Dahlias for show, for beds, as single specimens.

The first question can be answered very shortly.

Experience alone can determine whether Dahlias will flower best from old tubers, pot tubers, or freshly-struck cuttings. Mrs. Peart only gives high-class blooms from old tubers, whilst Mrs. F. Fell flowers grandly from cuttings and pot tubers. The second question also is determined by experience, note being taken of what is required from the plant. Numerous small flowers are often of more value than three or four large ones. For show, size is an element of success as well as fine form, but there are varieties, such as Arachne, which form better show flowers with me if left severely alone. The third question as to shade and protection is largely a matter for the convenience of the grower, but it may be conceded "that all delicate tints with a rosy foundation will have the reds intensified if exposed to sunlight." Take Mrs. F. Fell as an example. You will note that earlier I advise the variety to be tiffany shaded. Do this and it is of exquisite purity; expose it to sunlight, and a rosy suffusion spreads through the flower.

I will not enter into the question of raising Dahlias, nor the soil necessary for their successful culture other than that, any ground suitable for growing good Potatoes should grow good Dahlias. The ideal soil is, of course, new good loam with effective drainage and plenty of top-dressing when dry, and some manure dug well into the soil some time before the tubers are planted. In growing Dahlias for show or to produce the highest class of flowers, it is advisable to place them in a plot of ground set apart, and convenience usually relegates them to the kitchen garden or an out-of-the-way ground. If this be done it is easy to protect them from winds, hot sun, or other Dahlia terrors by growing them in rows on lath trellis facing north and south, sufficiently, but not too close, and sowing all round the outside early Scarlet Runners on high sticks or trellis. You thus combine the useful and the ornamental, each row shading and protecting the one behind it efficiently. Add to this tiffany over those requiring such special care, and nothing more in the way of shade or protection is necessary, but the enormous evaporation from such an expanse of foliage requires continual moisture round the plant, and this is best supplied by heavy mulching (not necessarily manure) and, at least in dry weather, a daily watering, not forgetting to stir the soil and give liquid manure three times weekly when the flowers are beginning to form. For beds and borders where the natural beauty of the plants should be a first consideration, use strong hazel pea-sticks regulated to the height of the plant as it grows, commencing with branching twigs and adding more and taller until the plant when fully grown is supported by a framework invisible, but perfect. It is a revelation to see a variety such as Arachne find its way through and completely hide every vestige of a forest of Pea sticks, arranging itself naturally and defying rain and wind. Unless your stakes are very well put in, a central support gives stability and may be used if your plants are much exposed to wind, and your Pea sticks may be caught together with a little string and fastened to the central stake. If it be desired to grow fine single specimen plants on lawns or borders as standards, select one of the tall, strong-growing varieties, of which a list is given below, and, starting in heat an old tuber, plant it out as early as possible, training to a stout stake a single shoot only and removing all root suckers. Then pinch off all side shoots, keeping only the main stem, and at the desired height, say 5 feet, permit side shoots to grow, carefully tying these to Hazel twigs attached to the central stake. A head may thus be formed of sufficient size, and carrying for three or four months a numerous and beautiful collection of choice flowers. With a plant such as this special preparation should be made for its reception, a hole previously dug, heavily manured, and good loam if procurable added. Plenty of water when dry and liquid manure freely given will ensure a continuous blooming of exceeding richness and beauty.

Below is a representative list of Cactus Dahlias, comprising the choicest at present in cultivation and a selection from them of those best suited for training as standards.

Names.	Colours.
Mrs. Peart	White.
Mrs. F. Fell	
Keynes' White	Yellow.
Lady Penzance	
Matchless	Dark maroon.
Cycle	Cerise.
Starfish	Orange-vermilion.
Francis Humphreys	Orange.
Beatrice	Mauve.
Island Queen	Purple.
Earl of Pembroke	
Mrs. Wilson Noble	Pistachio nut colour.
Countess of Lonsdale	Scarlet.
Gloriosa	
Captain Broad	Red.
Fusilier	
Lucius	Light scarlet, shaded carmine.
Clown	Red, white tips.
Fantasy	Red.
Arachne	White petals, red edge.
Bridesmaid	Primrose, mauve tipped.
Mrs. Dickson	Bright and pure rose.
Leonora	Crushed strawberry.
Bertha Mawley	Rose, bluish tips.
Iona	Buff.
Sirdar	Crimson-maroon.
Harry Stredwick	Very rich maroon.

FOR STANDARDS.—Gloriosa, Iona, Beatrice, Cycle, Francis Humphreys, Keynes' White possibly, Starfish, Fusilier.

Old Parsonage, Grosford. P. H. MULES.

Eredium guttatum.—This species has now been flowering continuously for several months, and still the slender spikes may be seen emerging from every growth the plant contains. The flowers which are white and blotched with a dark spot in the upper petals after the manner of those of some species of Pelargonium are numerous on every spray, and scarcely a day passes but a few fresh blossoms expand. The plant is best suited to the rock garden and is of a neat, attractive habit.

Yucca recurva.—This is probably one of the most graceful and attractive Yuccas in cultivation, and is also known under the equally appropriate name of *Y. pendula*. For lawns, vases, or the central figure of a bed it is probably unrivalled. The beautiful straight sword-shaped leaves are at first more or less erect, but with age they gradually assume a graceful drooping habit, which is in fine contrast to the young erect ones in the centre. In addition to the grace and symmetry of the foliage is the soft sea-green colour, with a beautiful glaucous hue on the upper surface. Grown in good soil and in a sunny situation *Y. recurva* soon becomes very symmetrical in outline and at once arrests attention.—JOHN WEATHERS.

Permanent beds of fine-foliaged plants.—Three at least of our hardy trees readily lend themselves to the formation of these, for if the Stag's-horn Sumach, Paulownia imperialis, and Ailantus glandulosa are planted young and cut back close to the ground during the winter, they will on the return of spring push out several stout buds. Three or four of these may be left on each plant for a little, when if all but the most favourably situated one are removed it will grow vigorously, and produce leaves of a size unknown when the plants are given ordinary treatment. This same process may be repeated year after year, hence if a bed is planted with either of these subjects, it will with little trouble at least equal the tender sub-tropical plants that are so much employed during the summer. A characteristic illustration of a Paulownia imperialis so treated is to be found in vol. I. of THE GARDEN (p. 518—T).

Galanthus cilicicus.—A number of people have a prejudice against the Snowdrops which come into flower in late autumn or early winter. They look upon them as unseasonable, and as

lacking the associations connected with the common Snowdrop. I should be one of the last to deny that the Snowdrop owes much of its interest to the legends and poetry which are inseparably connected with its appearance in the dawning of the year; yet I think we may well find a welcome for its precocious sisters, which brighten duller days when we can hardly avoid feeling that even a single flower in the garden is very precious. Thus I enjoy the first of the Snowdrops—*Galanthus eliiensis* (Baker)—which came into bloom here on October 27. I hardly expect that it will flower so early another season, but believe it will appear before *G. octobrensis* and the few others which generally open before Christmas. None of these are yet through the ground here, but the *Gilvian* Snowdrop is fully open. It is more robust than some of the others. It differs from these (with the exception of *G. Elsie*) in the absence of the glaucous line down the centre of

useful for cutting. Single yellow *Marguerites* of small size are often very useful for cutting, and late in the season they are none too plentiful.—S. ARNOTT, *Carsathorn, by Dumfriesshire, N.B.*

October flowers in the open garden.—Borders and beds are now (middle of October) very gay. The following are amongst the best: *Lobelia Queen Victoria* is a glorious mass of colour rising out of a carpet of Tufted Pansies. Japanese *Anemones* are full of bloom, and from 3 feet to 5 feet high. *Michaelmas* Daisies in a dozen or more kinds are making a brave show. *Marigolds* never gave better returns. *Pentstemons*, too, are flowering freely. *Dianthus*es sown in April are still gay, and the same may be said of *Phlox Drummondii* and white *Antirrhinums*. *Phygelius capensis* is very gay with its long spikes of *Pentstemon*-like blooms. In warm situations *Zinnias* are still gay. *Sternbergia lutea* makes a show with its bright yellow blooms

the smaller plants from a large lot, the best of which had already occupied a large bed. It is quite possible that such plants as this *Starwort* suffer greatly during transit. This would be especially the case where much leafage remained on the plants when packed, and naturally such things would take a long time to recover. So far as my experience is concerned, I have never had any difficulty in growing the plant in any of its forms, but at times, owing to the slugs, considerable mischief is done. I have not noted these have a fondness for particular varieties. Broadly speaking, I consider the alpine *Aster* amenable to cultivation in any good ordinary well enriched soil, and in the light soil of this district (Hampton) I employ cow manure very freely when planting hardy things. The plant in question by its dwarf habit of growth would be grown in company with the dwarf alpine and other *Phloxes* and other such things, with no attempt in the least to specialise in respect to soils. This endeavour to imitate natural soils has doubtless been much over-estimated, and to a large degree is not needful in British gardens.—E. J.

Gunnera at Countesswells, Aberdeen. From a photograph sent by Miss Pirie. (See p. 385.)

the leaves.—S. ARNOTT, *Carsathorn, by Dumfriesshire, N.B.*

Anthemis tinctoria (Mr. C. E. Buxton's variety).—In spring, Mr. C. E. Buxton informed me that he had in his garden at Coed Derw, Bettws-y-coed, a seedling *Anthemis tinctoria* of unusually free-flowering habit which continued in bloom long after his other plants had gone out of flower. He very kindly sent me a plant so that I might test its habit under conditions different from those in his garden. This I have done as carefully as possible. The plant has had very few flowers cut from it and has been allowed to form seeds from its earlier blooms. Notwithstanding this, it has still a number of blooms open and buds in various stages of growth which give promise of flowers for a considerable time should the weather not become too severe. All my other plants of *Anthemis tinctoria* have been out of bloom for some time, and some have been cut over for late flowers should the season prove an open one. Mr. Buxton's variety thus gives every promise of being an acquisition, especially as the flowers are of good form and colour and very

against its green leafage. *Fuchsia gracilis* and *F. corallina* are full of bloom. Autumn *Crocuses* on the grass are doing well, and the white *Everlasting* Pea still gives a few flowers. To-day (November 1) I cut a good handful of bloom. Both *Salvia splendens* and *Betheli* are making the border gay in a warm spot. The same may be said of *Cuphea platycentra* and *Calecolaria amplexicaulis*. Dahlias are quite a show, and at no time this season have they looked so gay.—DORSET.

Aster alpinus.—With reference to these pretty *Starworts*, I would certainly advise Mr. Herbert Millington to forego the imported plants in favour either of home-saved seed or home-grown plants. When I stated that I regarded this as one of the easiest of all alpine to cultivate it was no exaggeration in the least, as I have raised many hundreds of plants, and in quite ordinary loamy soil planted out edgings of the seedlings at least 120 feet long in a single line. This was so done more from economic reasons and the value of the beds wherein better things were planted. The plants thus lined out were

NOTES AND QUESTIONS.—FLOWER.

Dahlia White Aster.—This pompon I find most useful. I am aware it is somewhat formal in outline. It is a most profuse bloomer, and a great recommendation to it is that it throws its blooms up on long foot-stalks out of the leafage. For cutting it holds a most important place. At the end of October it is giving me good blooms.—DORSET.

Mignonette Machet.—This *Mignonette*, even during the greater part of the long period of drought, continued to blossom most satisfactorily. Owing to the change to rainy weather, new growths developed and flowers were again plentiful. I have before me a vase filled with spikes of bloom, and should the weather remain open there is promise of a goodly display for some time.—D. B. C.

Sternbergia lutea.—If Mr. Arnett, who in your number of October 22 mentions with regret his inability to bloom this plant, will try the following plan, I think he will find it as successful with him as it is with me. Plant *Sternbergia lutea* in a narrow border fringing one of his hothouses; let the position be sunny and the soil light; never give any water artificially, or, at any rate, not until the foliage is showing well. In such circumstances I flower this *Cape Crocus* regularly, and it is now blooming alongside *Zephyranthes candida*, which grows like a weed similarly situated.—HERBERT MILLINGTON, *Broomgrove School, Worcester.*

CHRYSANTHEMUMS.

THE CHRYSANTHEMUM RUST.

A good deal of attention is just now being given to the new fungoid disease which has attacked the *Chrysanthemum*. It is familiarly known as the "rust," as to the proper classification of which doctors differ, but which all the same seems to have created alarm in the minds of those growers who make the *Chrysanthemum* either a medium for trading or to win prizes by producing gigantic flowers under artificial conditions of culture. But amidst all this concern there is comfort for all those who like to have *Chrysanthemums* blooming in their gardens in the autumn, because it is authoritatively stated the rust does not affect plants naturally grown. It is only the pampered pets of the growers, those that are highly fed and rendered because so treated fit subjects for all fungoid attacks, that suffer. It seems only needful to observe natural conditions and the trouble is non-existent. When we grow *Chrysanthemums* in the open ground their primary requirements are plenty of room, fairly good deep soil, with which is incorporated in the early summer some ordinary manure. If it be desired later, some thinning of the blooms may take place, and Nature will not resent it. It may be

urged that *Chrysanthemums* outdoors give no winter bloom in the same way that plants do grown in pots specially for the purpose. That is so; but even then it is practicable to have plants that can be prepared for housing and furnishing bloom late if desired without violating natural requirements. Young plants propagated by cuttings from others that have wintered out-doors are, of course, quite clean and hardy. These may be grown on without forcing into strong plants of bush form, and be got into 8-inch pots, then may be plunged into the ground in an open position and thinly, being kept watered as needed, but not fed with artificial manures. The roots would run out of the pots into the soil. If the varieties so grown are naturally late bloomers, that may be left till the middle of October, and even then be stood in a block so that for a time they may be protected from frosts and heavy rains by means of a roof of framelights or oiled calico, then they can be housed later. Flowers in abundance from plants of earlier varieties may be had by growing some in the open ground, lifting them into large pots and standing them in a greenhouse early in October. If the early and late autumn-flowering varieties be also liberally grown, and a wonderfully beautiful selection of these can be had to bloom from August till November, how easy is it to have *Chrysanthemum* blooms of good quality abundantly produced for fully six months of the year without employing any expensive or artificial treatment, or of adopting a system of fattening that may be excellent for Cabbages or Rhubarb, but is most injurious to ordinary plants. It is not much to our credit as a nation that we should have elevated the *Chrysanthemum* into a description of fetish.

A. D.

CHRYSANTHEMUMS AT LEWISHAM.

THOSE who have visited Ryeeroft know full well the floral treat in store for them at this season of the year when there are three large greenhouses full of flowering plants such as one could hardly expect to find within the smoky zone of the metropolis. Although situated in the south-east corner of London, visitors can now book to Hither Green Junction from any station on the South-Eastern Railway, and this is far handier to Mr. Jones's nursery than going to Lewisham Station, as of old. The Ryeeroft *Chrysanthemums* are in finer condition than last year, when, unfortunately, a few weeks before the opening of the *Chrysanthemum* season Mr. Jones was unable through illness to personally superintend the finishing touches to his large and varied collection just when it needed his supervision the most. This year, however, will in a measure be a compensation, for we understand that troublesome pest the rust has put him to little or no inconvenience, and his flowers are certainly in a most promising condition. This is all the more satisfactory for another reason. Year by year the neighbourhood, which was not long ago very open and rural, is now being fast covered with houses, a fact that in spite of the *Chrysanthemum* being called a town flower materially increases the difficulties of cultivation, and places a grower at a disadvantage with his more favoured rivals who live far away in the open country.

We do not wish to make a mere catalogue of names, but it is difficult to deal with such a collection as this without mentioning more or less briefly many of the most striking and effective novelties, and of these we may say that amongst miscellaneous varieties from various sources the following are of a high order of merit: *Chrysanthemista* Bruant, a big golden-chestnut-bronze Japanese incurved; Mme. Leon Fejerick, deep golden-ochre-yellow, with broad florets, forming a good Japanese incurved; Rayonnante, an exag-

gerated and finer Lilian B. Bird; Miss M. Donaldson, a true Japanese of a delicate shade of pink, pretty, but not over large; and Dr. Noel Martin, a creamy white Japanese. Others such as Emile Nonin, golden-chestnut incurved; Comtesse de Boulaincourt, yellow Japanese; Abbé Brosson, large white Japanese; Fleur de Lilas, pretty rosy pink, medium size, and a few more are not commonly met with, but deserve to be mentioned. The novelty-hunter may do well to keep a lookout for such as M. Caillebotte, purple-amaranth; Sita, Tatiana, a fine yellow; La Mareadion, incurved reddish chestnut and golden buff, upon whose merits it is perhaps premature at present to pronounce.

The seedlings received from M. Ernst Calvat during the past season or two comprise a grand looking incurved called Topaze Orientale, beautifully built, very deep in form, and of a pleasing shade of clear pale yellow. François Coppée is of a deep golden shade, with long florets. President Bevan, a noble flower of its type, is big and massive, with numerous narrow grooved florets, closely incurving, and of a deep golden-bronzy shade. Marie Calvat is rather rough and loose, a long petalled Japanese, colour white, faintly tinted. Le Grand Dragon is one of this season's novelties, very fine long florets, drooping, and of medium width, a rich golden-orange-yellow, faintly streaked with red. The green novelty, Mme. Ed. Roger, is curions, and Secrétaire Rivoire is a pale yellow Japanese. One of the noblest and best of Calvat's 1898 seedlings is M. Fatzler, a Japanese of great size and substance, the colour a deep rich pure golden-yellow. Mélusine is white, streaked purple, large, but not very taking, while the same cannot be said of General Paquic, which has flat recurving florets and is of a very pretty and distinct shade of golden terracotta. President Nonin is another somewhat similar in build and colour. M. Hoste is older, a large white Japanese, tinted purple.

Some of the colonial varieties here, as elsewhere, do credit to the raisers in the Antipodes, who seem to understand the kind of flower most likely to appeal to English tastes. Oceana, Australie, and Pride of Madford are all well known, and to them must now be added Chatsworth, a fine deeply-built Japanese, of pale pink; Mrs. H. Briseoe, a large Japanese with long florets, colour pretty rosy mauve, with reverse of silver; Miss Mary Underhay, one of the finest and best, and of a lovely shade of rich buttery yellow, an incurved Japanese; Beauty of Adelaide, long florets, colour rosy pink; Nellie Poekett, white; and Miss Vera May Fraser, a charming shade of golden terracotta, with a golden reverse. Very pleasing, but only of medium size, is the graceful pale pink Mrs. F. A. Bevan. Mr. Peter Keary, a Japanese with drooping reflexed florets and of a fine shade of velvety purple, reverse silvery, is also most attractive. A deep golden yellow sport from the well-known Edwin Molyneux ought to be a good thing judging by its present appearance, and for richness of colour, Royal Standard, a striking bright crimson and gold Japanese, is at once effective and rich. A few others of the best are Mrs. A. J. Baker, large and globular, narrow florets, curly at the tips, colour pure paper-white; Duke of Wellington, big, solid, and globular, a Japanese incurved, with broad florets of rich golden bronze; Mrs. L. Humphrey, large Japanese, colour pale primrose or canary-yellow; Lady Hanham, Mr. A. Barrett, quite distinct from Mrs. G. W. Palmer, the sport from Mrs. C. Harman-Payne, and several others in which, perhaps, individual taste will play a large part in allotting the position they should occupy hereafter.

It may satisfy some inquirers if we say that at Ryeeroft there is an unquestionable difference in the two yellow Carnot sports. Both are grand blooms, but G. J. Warren is certainly several shades deeper in tone than the pale primrose-yellow of Mrs. W. Mease, which to our taste is by far the more chaste and pleasing. Mrs. W. Popham is big, solid, and substantial, a Japanese incurved, very deep in build, colour pale purple,

with silvery reverse. H. T. Wooderson, of the same section, is close and compact, colour bright deep rosy pink. In yellows, Lady Oporto Tait is large, and Mrs. Maling Grant, different in form, is deep golden buff, streaked bronze. Princess Charles of Denmark is golden yellow. Mrs. J. W. Barks is a fine bronzy yellow sport from Edith Tabor. Very deep in its own peculiar shade of shiny, glistening golden yellow is J. Hooper Pearson, a Japanese with rather broad grooved florets. Lionel Humphrey, of the Japanese type, is large, with flat drooping florets of great length, colour deep crimson-chestnut with a golden reverse. Robert Powell, Julia Scaramanga, and Vicar of Bray are but varying and deeper shades of the primary colour of our popular flower.

CHRYSANTHEMUMS AT SYON HOUSE.

THE collection grown at Syon may be regarded as among the most extensive, as it is indeed also representative. At the time of my visit—paid somewhat early in the hope of seeing the flowers at their best—a large number of the finest examples had been cut, yet ample material remained to show how well the entire collection had been grown. Happily, too, the dreaded rust has not as yet appeared, though, with praiseworthy frankness Mr. Wythes stated a few specks had been seen, and as quickly and promptly destroyed. Indeed, in the procuring of many novelties from time to time, and from varied sources also, he would be bold indeed who could aver so large a collection was absolutely clean. It may not be out of place to give a hint concerning a cultural item which Mr. Wythes regards generally with favour, not merely in the cultivation of the *Chrysanthemum*, but in various other departments also. It is the free use of soot water, in itself a safe and timely as well as more or less natural stimulant. This simple, yet too frequently neglected, stimulant is made part and parcel of the daily cultural routine, with results that are abundantly clear in the flowers. Weak solutions of soot water are employed for syringing from quite an early stage, and later applied also to the roots. So obvious is all this, that the virtues of the solution may be taken for granted; indeed, in another department a recent application on a splendid lot of Malmaison Carnations rendered the plants quite dusky looking. It will be remembered, however, that a "rust" so called, in some respects similar, attacks the Malmaison section of Carnations, and the solution in this instance had been applied from a preventive point, and as there were some 2000 of these Carnations the picture of health, the value of soot as a preventive means, and not the cure itself, appears to possess weight. The *Chrysanthemums* grown at Syon number about 1500 plants, 1000 of these bearing from two to four flowers each, while the remaining 500 are grown as bush plants for late bloom. The whole of the plants are in 10-inch pots, and in the abundance of fine foliage alone there is ample proof of careful daily attention. The collection, itself rich in the novelties of recent years, is equally rich in the tried older and still indispensable flowers, while it is replete with good kinds that are of known value for forming bush plants and for providing a lasting display of flowers. In so large and representative a gathering it will not be possible to name even a small proportion of the kinds grown, so that a few of the more conspicuous at the time my notes were taken will suffice. Many kinds, even of the large-flowered forms, were not sufficiently advanced to form an opinion concerning them, a fact which may be taken into account. Three of the finest white kinds, Beauty of Exmouth, Avalanche, and Elaine, were in strong force, and as a trio among early whites very difficult to beat. As previously noted, hundreds of the finest flowers have been cut, yet of the first-named there were examples that could scarcely be surpassed. Another white, evidently a favourite here, is the white Louis Boehler. These with Mme. Carnot are among the chief of the white kinds, and each represented by hatches of hand-

some, well-proportioned flowers. Very strong, too, is *Pride of Madford*, the foliage especially good, and each plant bearing a full complement of blooms of this striking colour. The newer variety *Australie* was grand in the extreme and will take a lot of boasting in this way. The peduncle of this kind is wonderfully strong. A splendid lot of this, with violet-amaranth shade and silvery reverse, told its own tale. Yellow and golden yellow shades were well to the front, such kinds as *Amos Perry*, *Phœbus* (new, one of the best finished flowers yet sent out), *Sunflower*, *Kentish Yellow*, *Oceana*, a most exquisite shade of colour, being in fine form. *W. H. Lincoln* was in plenty, but as yet not at its best.

Among the deeper shades, *Robert Owen* was most telling, the fine build and splendid incurring properties of this flower being seen to advantage. *Charles Davis*, *Charles Molyneux*, *Comte de Germiny*, *Vivian Morel*, *Ada Prasse*, *H. Shoemsmith* and *General Roberts* are kinds so generally well known as to need little description. *Col. Smith* was very fine. *Mme. C. Champion*, a beautiful lilac-mauve, very handsome; *Mrs. Libbie Allen*, fawn and bronze; *Lord Brooke*, *Condor*, flesh-pink and much esteemed here; *Ada Spalding*, *Inter-Ocean*, *Charlotte de Montcabrier*, lilac and flesh tint; *Edwin Molyneux*, *Mrs. C. Orchard*, *Stanstead Surprise*, very fine, and *Charles Wagstaff*, a most compact and well formed white, were among the best of the more advanced flowers. *Mrs. H. Fowler*, a grand yellow, was fast approaching its best, and is one of the many kinds of sterling merit to be found in this fine lot of plants. Many novelties are in a less forward condition, yet all give promise of a fine harvest of bloom.

CHRYSANTHEMUMS AT CHELSEA.

Those who regard the *Chrysanthemum* as peculiarly a town flower cannot do better than pay a visit to Messrs. Veitch and Sons' nursery in the King's Road, Chelsea. They will see there a very choice collection of well-grown plants, all of which have proved their fitness for cultivation in a neighbourhood surrounded by bricks and mortar. In some varieties, as might be expected, the deeper and richer tones of colour cannot under any circumstances be obtained unless the plants are grown in a more open and favoured position. In one house there are some pretty freely-flowered bush-grown plants for decoration, comprising such varieties as *Mlle. B. Vigny* (an old white), *Mabel Douglas* (yellow), *October* (yellow), *Comtesse Foucher de Careil* (golden terra-cotta), *Wm. Seward*, and several more. *Calvat's* seedlings are finely flowered, one of the best being *Louise*, which is big, massive, and of good substance. *President Nonin*, an incurved Japanese of fine form, buff-yellow, with a straw reverse, is very large. The rich golden-yellow *Amiral Avellan* is also of good size, and, like most from this source, helps to maintain the reputation of this well-known raiser. *Werther*, a deep rich velvety purple-amaranth, is fairly well-known, as also is *M. C. Molin*. *General Paqué* is another very large Japanese of a deep orange-yellow, shaded bronze, and having very long florets. *President Borel* and *Mme. Gustave Henry* need no description. One of the older sorts is *Mme. Marius Ricoud*, a very pleasing shade of deep rosy pink, and *Mme. Ferlat*, a finely incurved white variety of large size, leaves little or nothing to be desired. *N.C.S. Jubilee*, pale silvery pink, and *Souvenir de Molines*, orange-bronze, are also worthy examples of *M. Calvat's* skill. *Miss Nellie Pockett*, of Australian origin, is a very pretty Japanese, with a multitude of very narrow, grooved, incurved florets, pointed at the tips, colour pure white. *William Towers* is a large spreading flower, with long drooping florets of medium width, and the colour is very pure pale canary-yellow. The large white *Lady Byron* is in good form, deep and solid; so, too, are *Sunflower* and *Robert Powell*, both fairly well known. *Modesto*, the rich deep golden yellow American introduction, is very fine in colour and size.

Amongst the miscellaneous novelties of a few seasons ago received from the Continent *M. Aug. Lœvievier* is rather early, but of a peculiarly delicate blending of colour. *Baron Hirsch*, *Hairy Wonder* and *William Seward* are also noteworthy. Good whites are represented by *Mrs. H. Weeks*, *Mrs. Chas. Blick*, and *Mutual Friend*, while higher tones and varying in degrees of richness are *Octoroon*, *Royal Standard*, *Ethel Addison*, *Charles Davis*, and its parent *Vivian Morel*. *Descartes* in the Japanese *Anemone* section, deep rich velvety wine-coloured, is invariably good. *Mrs. R. C. Kingston*, a large pale pink incurved, is of fine build and very solid. Among other varieties that will attract attention, *Locarie Gentils*, the pale yellow sport from *Enfant des Deux Mondes*, *Mrs. S. C. Probin*, *Col. W. B. Smith*, *Mrs. Falconer Jameson* and *John Neville* are worthy of mention.

NOTES AND QUESTIONS.

Chrysanthemum Snowdrop.—Some two years ago this was frequently met with in gardens, and I was pleased to see it again a few days since at Rousden, where it is grown in quantity, it being in demand for button-holes. It is about the smallest *Chrysanthemum* I know. It is late blooming, but the plants at Rousden that are in flower had been placed in heat to forward them.—DORSET.

Chrysanthemum Mrs. W. Mease.—No less than three trade growers exhibited this latest sport from *Mme. Carnot* at a recent floral committee meeting of the National *Chrysanthemum* Society. There is now not the slightest doubt as to its distinctness. Although described by the compilers of catalogues as a sulphur-coloured flower, this hardly meets the case. After carefully comparing the blooms with others of a pale primrose tint, this appears to be the more correct description of them. When contrasted with the other members of the family, viz., *Mme. Carnot* and *G. J. Warren*, the effect is particularly pleasing, the soft primrose of the sport being most pronounced.—B. C.

STOVE AND GREENHOUSE.

THE AUSTRALIAN SPEAR LILY.

(DORYANTHES EXCELSA.*)

This singular plant grows, in its native state, in one limited district of New South Wales, but fourteen years ago a small plant was brought from the Antipodes by *Colonel and Mrs. Hill James*, smuggled into Algiers, and placed in the lovely garden of the *Rev. Edwyn Arkwright* at *Mustapha*, on the hills overlooking the town and beautiful bay. Here it remained unnoticed until last year, when to the surprise of everyone, after this long period of rest, it threw out a stem which in the course of ten months attained the height of 9 feet, when the great bloom crowning the top began to open and continued in full flower from January to May of this year, a period of five months. It attracted much notice amongst the savants and French colony generally, and is probably the first instance of *Doryanthes excelsa* blossoming in the open garden on this side of the world. There are two varieties of this curious species—the one here spoken of, *Doryanthes excelsa*, and another of less grandeur called *Doryanthes Palmeri*, after a Prime Minister of the colony of Queensland, in which it grows.

Doryanthes excelsa produces a great crimson bunch of blossoms of the size of a large red Cabbage on the top of a straight Aloe-like stem, and the many Lily flowers of which this bunch is composed, each petal being about 5 inches long, open in succession, so that it remains in blossom for many weeks. As some of the

* Extract from the "Bulletin Mensuel de Biarritz Association."

flowers shrivel and die off, others open, and expose the inside of the petals, which is of the most delicate rose-pink, shading into the purest white, whilst the outside is, as has been said, a deep crimson. This plant usually takes about seven years to blossom, but the specimen in Algiers has required twice that period to throw out its magnificent and gigantic bloom—this probably from its being moved to another hemisphere. It will now, if it takes the ordinary course, blossom again in about four years, for it does not, like the *Aloe*, die after flowering. *Colonel and Mrs. Hill James* made a journey to the *Hllawarra* district of New South Wales for the express purpose of seeing this gigantic *Spear Lily* in its natural habitat, and they say that a more glorious sight than a view of this sandy table-land partially covered with the ever-present *Eucalyptus* and a profusion of these great *Spear Lilies* shooting up from the undergrowth at various heights up to 20 feet, their great crimson blobs showing amongst the decaying branches of the forest trees, could not be imagined, and richly recompensed them for their trouble on the journey. The *Hllawarra* district, in which the *Doryanthes excelsa* grows, is above the *Bulli Pass*, some seventy miles from *Sydney*, and it was necessary to go first by rail, and then by a country coach to a ramshackle sort of auberge, where a sandy track turned off into the open bush. Here, after some trouble and delay, they managed to hire an old grey pony and a four-wheeled carriage, much too heavy for him, with decayed harness patched and mended with rope, in order to traverse the dozen miles or so of sand to the head of the pass. Many times the poor beast came to a standstill in the deep sand, for the day was hot, and they had doubts about the chance of reaching their destination; but at length the great red blobs of the *Doryanthes* began to show themselves amongst the lower branches of the forest in this wildest and most picturesque of Nature's gardens. Then they knew indeed that they had not made their journey for nothing. It was a unique sight which they recognised that they were never again likely to contemplate. Hundreds of these great red blobs in all stages of opening had projected themselves from their bunches of spiked Lily leaves, which grow round the root, up to the lower branches of the neighbouring great Gums, where they blossomed in wanton magnificence. Having feasted their eyes to the edge of night, the *Colonel and Mrs. James* descended the pass from the table-land and slept at a little wooden inn near the sea, and in the immediate vicinity of some of the valuable coal measures of New South Wales. On the following brilliant morning, their jaded pony being much recruited by his night's rest and food, they mounted the lovely *Bulli Pass*, which is one mass of *Yuccas*, *Cycads*, and great *Tree Ferns*, to the higher plateau, where the lady made a water-colour sketch of the *Doryanthes* on the ground of its own solitary choice. Six or eight of the flowers were cut down with a clasp-knife, leaving about 6 feet of stem, and taken a day or two later in the net of the railway carriage from *Sydney* to *Melbourne*, where they were exhibited at a flower show in the great town hall, and attracted much attention. The flowers of these cut plants lasted for six weeks in water. The stem is a porous reed about the thickness of a man's arm, and the crimson cluster at the top consisted of more than 100 blossoms in the plant at Algiers, the time occupied in throwing out the stem and bloom being about fifteen months. It is worth remarking that the *Spear Lily*, true to its native habit, began the opera-

tion of blossoming at Algiers in January, the coldest month of the year, but, of course, the midsummer of Australia.

Begonia Moonlight.—I have not seen this useful variety for some years now, and I am afraid it is now entirely lost. It used to be grown extensively at the Royal Horticultural Society's Gardens, Chiswick, some years ago. It was raised by the late Colonel Trevor Clarke, and was one of the most distinct hybrids. I believe it was a cross between Dregei and one of the yellow tuberous varieties. It would make a fine companion for Begonia Gloire de Lorraine, being almost equally free. I never was able to seed it, though sometimes it had what appeared to be perfect female flowers. The foliage was of a rich deep green with a darker marbling, the flowers of a pale creamy white. I should much like to hear (through THE GARDEN) if anyone now cultivates this variety, as I am anxious to secure some stock. There are several other good winter-flowering Begonias which seem to have been entirely neglected since the advent of the tuberous kinds, which, though so showy in summer, are of little use for winter flowering.—H.

Bamboos in pots.—The fact that pot plants of Bamboos were used with considerable success at a late harvest festival leads me to suggest that they would be found very useful for church decoration at any time of the year when plants are required for the purpose; and, indeed, for any indoor work they form an excellent substitute for tall Palms in those places where facilities for acquiring and housing these are not available. If the purchase of plants for potting is not convenient, an inspection may be made of established clumps, and in the majority of cases the original plant will not only have developed into a dense, compact mass, but have partially colonised its immediate neighbourhood with clumps of smaller size alike in height and diameter, with growths varying from 2 feet to 5 feet or 6 feet in height. These are the clumps admirably adapted for pot work. They should be lifted carefully, not over-potted, receive a good soaking to settle the soil about them, and be kept always rather moist. I am writing of *Arundinaria japonica*, the only one at my disposal. There are doubtless others even better adapted for the purpose.—E. BURRELL.

Zonal Pelargonium Guillon Mangilli.—I doubt if there is a better all-round zonal than this old variety. It is a very reliable winter bloomer, and there is no trouble to cut good trusses from it from November onwards. For summer flowering it is excellent, producing large heads of bloom in great profusion all through the season if the plants when root-bound are occasionally fed with weak liquid manure. I have plants of it now in 8-inch pots carrying about two dozen trusses, and these have given me a lot of bloom for cutting from the middle of June, and will continue to do so up to the close of the autumn. For the flower garden it answers better than the majority of double kinds, not making such gross growth as many of them, the flowers resisting heavy rains fairly well. Cutting struck in April and grown along freely will make good plants in 6-inch pots for winter blooming, and one-year-old plants cut back early in May, shaken out a little when they break, and replaced in pots one size larger, will furnish a quantity of bloom during the dull months of the year.—J. C. B.

Carnation Mrs. Leopold de Rothschild.—This fine pink variety, which is also known as Mme. Thérèse Franco, has not proved quite such a profitable variety for market as was anticipated, and I find some growers are discarding it altogether. I never thought it would produce anything like the quantity of bloom Miss Joliffe does. It certainly is not a robust variety, and does not keep up a succession of bloom. I have known it since it was first introduced, but have never seen it better than it has been this season, ther in regard to growth, size of flowers, or colour,

thus showing that it is not so much inclined to deteriorate as many varieties are. I find that one great secret in keeping up a vigorous and healthy stock is to be careful in selecting the best plants for taking cuttings from. Those that are grown on from year to year for flowering in pots gradually get weakened, but if a few of the strongest plants are selected and grown on without allowing them to bloom, they will give strong, healthy cuttings which will give little trouble in propagating, and under good treatment increase in vigour. This, of course, applies to all the Tree Carnations that are grown for winter flowering.—A.

GERANIUMS FOR WINTER AND SPRING BLOOMING.

WITH the many and beautiful varieties of zonal Geraniums now in commerce, a house having a comfortable temperature can now be made very gay during the dull months of winter by specially preparing the plants for the purpose. For producing plants for winter blooming, the best way is to take stout cuttings in February. When rooted, grow them on as hardy as possible, shifting into 4½-inch pots before they become pot-bound, keeping them close to the glass and giving abundance of air. At the beginning of June stand them in a sheltered position in the open air on a bed of ashes, pinching the growths when of sufficient length, and assisting the roots with liquid manure as soon as the 6-inch pots, which will be large enough for the plants to flower in, are becoming pretty well filled with roots. A good fibrous loam and some coarse sand suit them well. Keep all summer trusses of bloom picked off, and remove into a temperature of 50° early in October. Their somewhat root bound condition will induce flowering better than larger pots at this season. Even during the winter a gentle current of fresh air must be given in open weather to prevent the plants becoming drawn. For the production of large quantities of bloom during April, May, and June, plant out spring-struck cuttings along the edge of a Peach house or vinery border, allowing a distance of 2½ feet between each and planting in a compost of good holding loam and a little leaf-mould and coarse sand. This mixture not only produces a short-jointed firm growth, but also allows of the plants being lifted in autumn with a good ball attached. Pinch the growths as soon as sufficiently advanced and train the plants by means of stout wooden hooks or pegs. Continue this practice till the end of August, never allowing the plants to suffer from want of water. About the middle of September well water the plants, and a few days later carefully lift each with as much soil as possible and pot firmly into 10-inch pots, placing in a frame and keeping rather close for a fortnight. When established in their new quarters, give plenty of air, and in October remove to a cool, airy position in the greenhouse, or even a cool vinery or Peach house. When growing freely in spring, assist twice a week with diluted liquid manure. Plants so treated will produce a plentiful and continuous supply of good trusses of bloom. It is best to throw away the old plants and raise a fresh lot every year. J. C.

Luculia gratissima.—This free-growing, sweetly-scented plant is usually described as a cool house subject, but to attempt to flower it without a certain amount of warmth only leads to disappointment. It will succeed either in pots or planted out, giving the greatest satisfaction in the latter position provided the border is well drained and the compost porous. Good fibrous loam and peat in equal parts, with a good quantity of charcoal and small pieces of sandstone, suit it well. A cold, dark conservatory is about the worst place to grow it in, the plant needing warmth to ripen the wood and for the development of the flower-trusses. A warm, sunny greenhouse or conservatory suits it, but the temperature ought not to fall below 50° at

night when the bloom-trusses are expanding in spring, or they are almost sure to fall. After flowering, the plants if robust may be well cut back, and when growth commences a fair number of the strongest growths only retained. More fail to bloom this plant through giving too little heat and light than from any other cause.—C. N.

Hoya carnosa.—Probably no plant in cultivation gives less trouble to grow well than this, though it is often seen in a flowerless and unsatisfactory condition through being grown in too much heat and moisture. As an ordinary greenhouse plant it is very satisfactory, and under these conditions I have it, growing pillar fashion, 10 feet or so up the front of a tall conservatory, the house being kept so cool during winter that it is no uncommon thing to have the soil frozen quite hard in the pots during severe frosts. This appears to have no ill effects, as I never saw plants flower more freely or have finer trusses than these do during the greater part of the year. Some of the old flower-stalks have been on the plants for at least fifteen years, and one can hardly say with certainty how long they will last, as it is only on very rare occasions that one finds a dead stalk. During the period mentioned these plants have only been potted once, and this seems quite immaterial to their health provided the drainage is all right. Their roots are confined to 9-inch pots, which are stood on the ordinary wooden stages, so that they have no chance of escaping into any soil but that contained in the pots. When they are potted the soil chosen is one half fibrous loam, one quarter peat, and the rest silver sand and broken brick in equal portions. Once in two years they get a top-dressing with similar material. A mistake made more often than it should be is the cutting off of the old flower-stalks after the annual flowering, thus destroying the chance of bringing the plants into a free-flowering state. Where this is done they are practically flowerless, as it is the old stalks which produce most of the blooms. During summer and while growth is being made water may be given with tolerable freedom, and occasional doses of weak liquid manure are enjoyed, but in winter the plants should be allowed to get dust-dry.—L. P.

GARDEN FLORA.

PLATE 1196.

HYDRANGEA HORTENSIA VAR. MARIESI.

(WITH A COLOURED PLATE.*)

THERE is now a considerable number of varieties of the common *Hydrangea* cultivated in our greenhouses, several new ones having been sent over by the Japanese nurserymen during the last few years, but the variety now figured is, I think, decidedly the most striking and effective. It was introduced from Japan about twenty years ago, and is one of the many first-rate plants sent home at that time by Mr. Mariès when collecting for Messrs. J. Veitch and Sons. Although so considerable a period has passed since its introduction, it is only quite recently that it has come into notice. The first time I remember to have seen it was in May, 1897, at the Royal Horticultural Society's show in the Temple Gardens. It was exhibited again last year in fine condition, and was to my mind the most striking of the new shrubs in the show. It is like the variety *Otakst* in having the centre of the truss filled with small perfect flowers, whilst a few only of the marginal ones are sterile. These are, however, far larger than in any other variety yet introduced, for they each measure 3 inches to 3½ inches

* Drawn for THE GARDEN in Messrs. Veitch's nursery by H. G. Moon, May 12, 1898. Lithographed and printed by J. L. Gouffart.

across. The colour, too, is very pleasing, being a pale pink faintly tinged with delicate mauve.

This variety is as easily cultivated as the others. In the gardens of the south-western counties of England and Wales, where the common *Hydrangea* succeeds so admirably out of doors, it ought to become a very striking feature. If it should prove to be a little harder than the type (which is never killed outright near London), it would make a welcome and useful addition to our rather scanty array of autumn-flowering shrubs, but of that there is no evidence yet. As a greenhouse plant it will, no doubt, soon become as popular as it deserves. Messrs. Veitch are now sending it out.

The following is a list of varieties of *Hydrangea Hortensia* known here at the present time:—

Aigaku, flowers light blue. New Japanese variety.

Ajsai, rosy blue to light blue. New Japanese variety.

Benigaku, rose-coloured. New Japanese variety.

Shirogaku, white, blue centre. New Japanese variety.

Thomas Hogg, pure white.

Otaksa, flesh-coloured.

Nigra, stem black-brown (syns., *H. cyanoclada* and *H. mandschurica*).

Variiegata, requires to be grown in warmth or on a wall.

Lindleyi (syn., *H. japonica roseo-alba*).

Acuminata (syn., *H. Buergeri*).

Stellata (with several sub-varieties).

Mariesi.

For a full account of the species of *Hydrangea* the reader may be referred to *THE GARDEN* for the latter half of the year 1896, p. 122.

W. J. BEAN.

THE WEEK'S WORK.

HARDY FRUIT.

LIFTING PEACH AND NECTARINE TREES TO CHECK EXUBERANT GROWTH.—This was alluded to some weeks back, as it pertained to trees under glass for forcing. It now applies with equal force to those outside, and if more of this work were done persistently from year to year we should hear less in all probability of gumming and other attendant evils, as gross wood of an unfruitful character. Some young trees which have filled their allotted wall space have this week been shifted to a greater distance apart, allowing from a foot to 2 feet more room between them. An old tree of doubtful endurance was first removed and room thus afforded for doing this. A check will thus be given which must under ordinary conditions result in a more fruitful state ultimately rather than rank growth. No fault can, however, be found so far, as the trees are bearing well but with a tendency to grow too strong. The soil being non-calcareous, more stimulating food has to be afforded to meet the deficiency, hence it will at times foster more strong wood than is desirable. When lifting these trees a few slabs are placed under each stem wherever there is any tendency to send roots downwards. It is a simple practice, but efficacious, depriving the trees of no beneficial plant food or moisture. Of course the trees so treated are watered freely afterwards so as to settle the soil, this being a better method of so doing than heavy treading.

FRESH PLANTING AND TRANSPLANTING.—Do not now lose any time in pushing this work forward. It is of more importance than starting thus early with the general routine work of pruning, however important that even may be. Take care, as aforesaid, not to let the roots suffer from exposure or drought. Raspberries are a case in point, the fine fibrous roots of which readily suffer from exposure, more so possibly than any-

thing else that could be named. Give no quarter to bushes of Black Currants affected with the mite. It will not ultimately pay to endeavour to bring them round. Even the plan of cutting down half of the stock every year, if ever so effectual, has to be seriously weighed where room is valuable. The better plan is to destroy the plants by burning completely and then obtain a clean stock, which should be planted in another part of the garden. Black Currants, if good plants, will give a profitable return the first season after planting. To the list of names given last week should be added the following: Of Raspberries, Superlative and Hornet, Carter's Prolific being the next best, and of autumn bearers *Quatre Saisons* is the best when it can be had true. For the autumn also do not lose sight of the cut-leaved (or Parsley-leaved) Bramble. Of Black Currants, Baldwin's Champion and Lee's Prolific are two of the best, whilst of Reds, New Dutch, Ruby Castle, Red Grape, and Late Rivers are the first choice, and of Whites the Transparent should be the choice. Of Gooseberries, the selection should be made of such as suit given localities as well as for special purposes. HORTUS.

KITCHEN GARDEN.

AUTUMN VEGETABLES.—Most of the Brassicas are now of good quality and turning in freely, the much-needed rains of late having been very beneficial. On the other hand, I fear the supply of green vegetables in many parts of the country is none too plentiful, but in this district both runner and dwarf Beans are plentiful. This will eke out the autumn supply, and the pods will keep fresh a considerable time if, when of full size, they are gathered and placed in a cool store, the stalk ends in water, adding a little charcoal to the water to keep it sweet. The supply of Cauliflowers is now fairly plentiful, but it will be well to protect the heads if at all exposed, as frost soon discolours the flower. Several degrees of frost may be warded off by drawing the leaves together. I have rarely ever had Globe Artichokes at this late season. Up to now the plants have not ceased to form heads, and these, like Beans, keep a considerable time in water with a portion of the stalk attached. The Michaelmas Pea has just been cleared. This is a splendid variety for latest supplies, and although in very light soils, owing to heat and drought, late Peas have not been a profitable crop, this variety has proved one of the most reliable. It will be well to draw soil up to the stems of all late-planted Brassicas, as doubtless the growth will be very susceptible to cold. I find the late-planted quarters most valuable for spring supplies. I have only this week housed the first Seakale for forcing, and even now it is none too ripe. The early lots of Coleworts I note are this year splitting badly in consequence of the rain. These will be of little use, and should be cleared as soon as possible. Later plantings are looking well, and the batches of Hardy Green Coleworts planted in September will now benefit by being moulded up well to the leaves to protect the stems. Treated thus they often pass through the severest weather with little injury. The same remarks apply to all late-planted vegetables. These need a little more care than those to be cut before Christmas. Autumn-sown Onions will benefit by dressings of soot, and in light soil they will have a tendency to lift themselves out of the soil. This should be prevented by treading or firming the plants on either side of the row. Spinach growing away freely will need frequent hoeings, and will well repay for feeding in the way of soot or liquid manure.

MUSHROOMS.—With a lessening vegetable supply from the open ground there will be a greater demand for Mushrooms. So far I have had an excellent supply from beds in the open, the seasonable weather during the past month having been in their favour. Heavy rains will now need to be guarded against, as should the surface of the beds get saturated the spawn will cease to run freely. Many large growers keep up a supply from beds in the open till quite late in the year. The beds in the house will now be in full bearing if made

early in September. I find the best beds are those made a month later and from now there will be no trouble in maintaining a supply. My previous advice as regards beds and temperatures will still hold good, and those who have not plenty of material at command for beds will find it best to make small beds and more frequently. Beds under cover, as the yield decreases, will be benefited by a little salt in tepid water or liquid manure at a temperature of 100°. By covering the surface for a short time with warm manure new growth will soon follow.

TOMATOES.—The plants grown for autumn supplies have done well so far, but with a change in the weather it will have been necessary to use a little fire-heat to dispel damp. Very little moisture will now be needed for plants bearing fruit that is ripening; indeed, with fully-grown fruit I have found it a good plan to cut the plants at the base and place on racks, there being enough moisture in the stem to finish the fruits. It will now be useless to leave plants against walls that have fruits in any state. Small fruits may be made use of for pickling. Those nearly full grown will colour if placed on a shelf in a dry, warm place. This applies to all plants in unheated structures, as the plants will not be very presentable after November is in. It will be well to give fruiting plants in forcing pits more warmth, air being given freely in fine weather, with a little on the back ventilators at night. Should insect pests be troublesome, as is often the case with winter Tomatoes, it will be well to fumigate once a fortnight with N.L. All fumigator. Where there is a good set of fruit, it may be advisable to give fertilisers once a week, and any fully-grown fruits will ripen if gathered. This will assist later ones to swell more freely, as the plants will not set more fruits after this date.

WINTER CUCUMBERS.—So far I have not taken a fruit from the winter plants; I mean those to provide fruit from December till March. My autumn supply is given by plants grown specially for the work. On these there is an abundance of fruit, as the plants, if strong, crop freely. Plants in fruit should get regular supplies of food. I always cut the fruits as they mature, as they keep fresh some time in water at this time of year. In the case of winter fruiterers a strong growth should be built up, encouraging abundance of roots, as without these there will be failure later on. Should the roots have filled the pots or root-space, it will be well to add turf or a top-dressing to keep the plants active. When the plants are allowed to fruit, only a limited number must be left. There must be severe thinning and attention to feeding with winter Cucumbers. It is well to lay in new wood even at this season or in midwinter, as the supply will soon cease if the wood fails. If the plants are now making wood freely, plenty of good fruit will be produced later. It will now be advisable to stop each growth. This will induce sturdiness, and as long as fruit is not allowed to set the plants will continue to make abundance of wood even at this dull period of the year. The temperatures must now be liberal. Strong plants with ample roots will do with less heat than often advised. Later on it may be well to give a few degrees more in the case of plants in full bearing. My fruiting plants are kept at 65° to 70° at night, those not bearing being kept a few degrees lower. At the same time there will be a great saving of fire-heat by covering the glass outside with mats or covers. I use Bentley's prepared sheets. These throw off rain and snow and keep the house quite 7° to 10° warmer. The day temperature should be 5° to 10° warmer than during the night, at the same time giving plenty of moisture. Regular fumigations are necessary. All water given should be of the same temperature as that of the house.

PREPARATION FOR FORCING.—With many, hard forcing is not a necessity, and the advantages are great, as by slow forcing much better material is secured. I am now busy clearing out the old material from between the Asparagus beds forced yearly, and filling in with fresh. This latter in

my case is ash leaves only. These of course give less heat than fresh manure, but are more valuable, as they last much longer. Now is a good time to collect leaves, and if they cannot be used at the time of collection, if placed in bulk and turned occasionally they will be good for mixing with manure. Leaves used in this way are most serviceable, as they prevent violent fermentation, which is so disastrous. Those who need Seakale or Asparagus, say, in a month or six weeks' time, will need to adopt other measures to obtain a quick supply. Great benefit will follow preparing some of the plants for the work in advance of forcing. Few now force Seakale in the old way by placing pots or covers of some kind over the roots and filling in with large quantities of manure. This had its advantages, as if the heating material was slow it gave better flavour than lifting roots and placing in strong heat. Seakale for supplies at Christmas should now be lifted. This will force more freely if left out of the soil a few days, merely covering with a mat. From this date all the strong roots should be saved, cut into lengths of 5 inches to 6 inches, and placed in the soil. These make fine planting material next spring. Rhubarb will force much better if lifted a short time and exposed, and in the case of Asparagus this forces well taken from its growing quarters into heat. More warmth is needed now than later on. To maintain a regular supply it will be necessary to lift roots every three weeks. Asparagus forcing by lifting roots is an expensive process.

S. M.

ORCHARD AND FRUIT GARDEN.

A VALUABLE WINTER WASH FOR FRUIT TREES.

For cleansing the stems and branches of all kinds of fruit trees from parasitic incrustations, scale, and the eggs of various insects, much experience has proved the efficacy and safety of a caustic alkali solution, of which the following is the original formula: For making a small quantity, dissolve half a pound of caustic soda in a gallon of water, then add half a pound of commercial potash (pearlash), stir well, then mix both to make five gallons of solution for use. Apply to large stems with a brush, to small branches and branchlets in the form of spray, either with a knapsack pump, or other appliance, when the trees are dormant. The formula was given to Mr. J. Wright a few years ago by Mr. Leonard Coates, a large Peach grower and nurseryman in California, and published in the "Journal of Horticulture." This led to experimental trials on different kinds of fruit trees in this country, and these proving completely satisfactory, the wash became extensively and systematically used by those fruit growers who had thus proved its efficacy. It was, and is still, regularly used in Californian Peach orchards as the best of all applications for destroying scale, which is there much more persistent in its attacks than in Britain; indeed, Mr. Coates remarked that he should find it extremely difficult to grow Peaches with any approach to satisfaction without spraying the trees with this caustic solution every year as regularly as they are pruned. It is applied at a temperature of about 120° Fahr., and has been so used to Apple, Pear, Plum, and, in fact, all kinds of fruit trees in English gardens, as well as to Vines under glass, but it has since been found effective when applied in a cold state. The superintendent of the Royal Horticultural Society's gardens at Chiswick was one of the first gardeners to use this wash extensively in England, and he attributes to it not a little of his remarkable success in growing fruit for Mr. Lee-

Campbell at Glewston Court, Ross. He found this wash, applied in the form of spray, not only destroyed scale and polished the stems of the trees, but in the course of a year or two the red spider and all kinds of insects vanished, the result, he concluded, and doubtless with accuracy, of destroying their eggs.

Mr. S. T. Wright has since proved at Chiswick that the wash will destroy red spider, and at the same time its non-injurious character to the stems of Vines and trees to which it is applied. The small pest, yet great enemy, had taken possession of some Vines in one of the houses just as these were starting into growth in the spring. Though the Vines had pushed growths about half an inch long and the sap consequently become active, the bold step was promptly taken to brush the canes thoroughly (not the young growths) with the caustic solution, forcing it into the fissures of the bark. Not the slightest injury was done to the Vines, while the spider was completely destroyed, and the house has been free from the pest ever since.

Other testimony of the value of the caustic wash on fruit trees is recorded by Mr. H. H. Cousins, M.A., of the South-eastern Agricultural College, Wye, Kent, in his excellent little shilling primer, the "Chemistry of the Garden" (Macmillan). The trees there referred to have been seen both before they underwent the cleansing process and since. A worse case of insect-infested and Moss-encrusted branches could not easily be imagined, nor a better cure, for all animal and vegetable parasites had been swept away. Mr. Cousins reduces the pearlash somewhat and adds soft soap. This is probably a good addition, but the wash is no better for the reduction of pearlash, and probably not so good for destroying the eggs of insects. It is something to know, however, that it is not absolutely necessary to incur the trouble of heating the mixture to render it effective, as though the heating might be easily done in some cases, in others it might be inconvenient. In the case of possibly immature Peach wood it might be prudent to increase the water from five to eight gallons and note the effects before using the full strength solution.

Protecting the stems of early-forced Vines.—The necessity for thoroughly protecting from cold the stems of early-forced Vines where they come through the front wall into the open air was proved by an incident which occurred some years ago in Suffolk. A gardener who had a house of early Vines found on entering it one morning during severe frost that the foliage, which had grown to a considerable size, was drooping, and had a half-paralysed appearance. Being at his wit's end, he hurried off to a neighbouring gardener—a very practical man—and laid his trouble before him. His friend returned with him to the viney, and after viewing the Vines went at once and examined the stems, which he considered were not sufficiently bound up for such severe weather. He advised pouring warm water on them and giving additional protection. This was done, with the result that the leaves soon began to recover, and in a short time presented their natural appearance, with no ultimate injury to the crop. Some gardeners, and I think it a good plan too, like to have a narrow border, say a couple of feet wide, inside the house in which to plant the Vines, allowing the roots to pass through arches into the outside border, thus saving the stems from exposure.—N. N.

Peach Marquis of Downshire.—At p. 273 "G. W." has a note on this Peach and recommends it for planting on open walls. "G. W." has not, he states, tried it under glass, but if he has space for a tree of it in a cool house I do not

think he will be disappointed. I referred to this Peach a year or two ago as being well grown at Kelham Hall, Newark. Mr. Webb, the gardener, has it on the back wall of an unheated Peach house, Royal George occupying the front trellis, and the situation being near the river and low, mildew often attacks the latter, but Marquis of Downshire always escapes. It invariably sets well, and as the fruit from these gardens is disposed of in the market the tree is allowed to carry as heavy a crop as possible. This it does year after year, and the flavour is good, even better, perhaps, than that of fruit grown outside. It is known at Kelham by the name of Royal Ascot. Has "G. W." ever given Desse Tardive a trial under glass? Both at Gunton and Blikling this Peach is thought well of as a late variety, a good-sized tree at the latter place having borne excellent crops of fine, well-flavoured fruit. I recollect Desse Tardive being sent out by the late Mr. Rivers, of Sawbridgeworth, and I was much impressed with the size and handsome appearance of some fruit growing on quite a young tree on the back wall of a Peach house near Brentwood. To my mind, it is one of the best flavoured of the late, somewhat thick-skinned varieties. "G. W." speaks well of the new late variety Devonian, and states that its quality is superior to that of Late Admirable. Grown under glass, however, I think the latter is of very good flavour. This Peach is very liable to be confounded with Walburton Admirable, a large late Peach of excellent quality.—B. S. N.

SOME MIDSEASON PEARS.

DOYENNE DU COMICE is becoming well known, and ranks as one of the very best Pears in existence. The fruits are of delicious flavour, fine in texture, large, and handsome. The tree makes healthy growth and ought to be planted freely on walls with various aspects in every garden, as it sometimes fails to crop on some of the trees while others are well laden. Even when all of them fruit together a glut will hardly be felt, as from the different aspects a succession may be kept up from October till nearly Christmas. Fondante de Thirriot is a handsome Pear which will doubtless be largely grown. Unfortunately, it comes in at a time when so many Pears are in season, for though it is called a November and December Pear my experience with it from a south wall, and with the fruits allowed to hang until they dropped of their own accord, is that it is ripe before the end of October. Possibly if grown on various aspects it might cover a long season, as the fruits keep well for a time after ripening and do not decay at the core. It is a very juicy fruit, sweet and pleasing, with no very distinct flavour. For exhibition it is grand, as the fruits are large, well shapen, and clean, pale green when growing and straw-coloured when ripe. Striking characteristics by which it may be readily recognised are the wrinkled base and the very long, medium-sized curved stalk. The tree bears freely and will carry a heavy crop. Another large and handsome Pear is Durondeau, an excellent cropper, the fruits of distinct but slightly rough flavour, well liked by many, but I cannot say that it is a great favourite here, and, except for market, not many trees should be planted of it in one garden, as I find its season rather short. It has something of the form of Beurré Bosc, being very long in proportion to its girth. Emile d'Heyst is a favourite during its season, which does not last long. It has a Banana-like texture, and in flavour and general appearance is very much like Marie Louise, but its form is more regular than in that popular variety and slightly fuller at each end. It is a handsome fruit when dished up, as the small eye stands out flush with the well rounded apex, and the rich golden brown hue is very striking. Princess is a first-rate Pear, also having only a short season. It is very much like Louise Bonne of Jersey, but fuller in form, not quite so long, and its season is later. The tree almost invariably crops well. One of the most reliable Pears grown by me is Conseiller de la Cour; this hardly ever fails to crop heavily, and

the fruits come clean and big. A certain roughness it imparts to the palate prevents it from being classed as a really first-rate Pear, but it has so many good qualities and lasts over such a long season without showing any tendency to decay at the core or to become sleepy that I find it an indispensable variety. In whatever form it is grown, it makes a very handsome tree, with pendulous, but sturdy branches and healthy leafage. J. C. TALLACK.

Apple trees unhealthy.—I shall be much obliged if you will inform me as to the best means of clearing in winter fruit trees which suffer in summer from a blight which shows itself in black blotches and patches on the leaves. A large proportion of the Apple trees in this neighbourhood has been badly affected this year, and trees of the hardiest sorts as well as delicate kinds have suffered. I generally use caustic soda from a sprayer two or three times during the winter, but this has not prevented the fungus coming, and I tried this summer the specific for Potato disease—lime and sulphate of copper, but without effect. Is it any use using some stronger solution during winter, or will the trees get infected from other trees and plants in the spring? I enclose some leaves gathered at two different dates, and shall be very glad if you can suggest any remedy. I am rather afraid of spraying the leaves early in the summer, as I have sometimes destroyed the leaves, although the solution was only of the recognised strength. This pest has during the past three or four years done very great injury to my fruit trees, of which I have nearly 1000.—APPLE.

* * * The leaves from your Apple trees appear to be attacked by the Apple scab fungus (*Fusicladium dendriticum*). You should collect and burn all the leaves that have fallen from the trees that have been attacked as soon as possible. In the spring, just before the leaf buds open, spray with Bordeaux mixture. Repeat the application just before the flower-buds open and again as soon as the blossoms have fallen, and then once more about ten days later. The following is a good recipe for the Bordeaux mixture: 1 lb. of sulphate of copper (bluestone) dissolved in 10 gallons of water in a wooden vessel, 1 lb. of lime, and 1 lb. of common treacle, boiled together in a quart of water for half an hour. When cool pour the lime and treacle into the solution of bluestone, stir well, and it is ready for use.—G. S. S.

Little-grown Apples.—"A. D." (p. 318) enumerates six varieties of Apples which drew but little competition, and one of them none at all, at the recent show at the Crystal Palace. Three of the varieties named I am not well acquainted with, but the other three I have grown for some years, and am at a loss to understand why two of them, Duke of Devonshire and Egremont Russet, are not more generally grown than at present. The former is a small fruit, but its shape and colour are very good, and when well ripened it will keep until April, when it is of excellent quality for dessert. This Apple should be allowed to remain upon the tree as long as possible, an old herring net being thrown over the tree to keep off the birds, which are apt to be troublesome. With me this year the crop was gathered on November 1, up to which date it had grown freely. Egremont Russet is a larger fruit than the last-named, and has a dull russet appearance when growing, but becoming almost yellow when fully ripe. James Grieve is a comparatively new Apple, it having been introduced to cultivation about ten years ago, and judging by the large number of trees that were last year despatched to England from its place of introduction in Edinburgh, it is probable that in the near future it will be much in evidence at autumn exhibitions. I have cultivated this variety for several years, and have found it to be one of the most prolific and constant fruiters grown, either as a bush or cordon. When planted against a wall the fruit is large for dessert, but from the open of good medium size and very well shaped. This

season it has coloured remarkably well, being at present almost yellow, with faint dashes of bright red about the upper part of the fruit, which gives it a very distinct appearance when staged.—JAMES DAY, *Galloway House, N.B.*

INJURY TO WALL TREES FROM WIRE.

THOSE who may possibly, like myself, have been troubled with the pernicious effects of galvanised wire upon Peach and Nectarine trees in particular will do well to adopt the following practice every year at about this time or a little earlier, say as soon as the leaves are falling freely. I go over the trees and cut every tie that holds them against the wire, and then bunch up the wood so that it cannot be broken down later on when snow is a possible occurrence; thus each stout leading growth supports its own younger ones. The former in turn are then slung loosely to the wires, so that the wood does not touch them. In order to effect this a wooden block is placed behind the main stem, so that it is sufficiently removed to create a resisting power when drawn back again. Since I have adopted this plan, now nearly twenty years ago, no trouble has ever resulted. Before that it was grievous to see the harm done every year to the young wood, so much so as to make some of the trees perfect skeletons. It took a season or two to find out when the injury was actually done. I used to think at first it was caused by heat, but this was in due time clearly proved not to be the case, as none of the wood was affected at the fall of the leaf, but was found to be so in the spring following. Upon closer observation then it was distinctly seen where the injury was caused and what also was the cause of it. Every shoot of the previous season's growth wherever it touched a wire or wires was practically killed through, leaving only that portion farthest removed from the wire in a sound condition. The cause beyond any question was the cold which acted in contact with the wires, resulting in the temperature being lowered below that of the atmosphere. Anyone can prove this for himself by holding galvanised wire in his hands at such times, when he will find the cold to be intensely penetrating. From observations taken at different times and seasons, I have arrived at the conclusion that both extremes of temperature have the same injurious effect; it is not caused when the wire is of a normal temperature. The last injury I noted was to some current season's shoots of *Dendrobium* noble which only lightly touched the wires. These were blackened at above and below the contact. Heat in this instance was the cause, it being intensified by the wire. Harm is not done to the Peaches and Nectarines by heat, as the shade imparted by the foliage is sufficient protection, but it is caused, as stated, by the directly opposite conditions. The bark of the current season's growth of Peaches and Nectarines is still soft, and hence liable to harm during the first winter. It does not become hardened, as in other trees, until the following season. Herein no doubt is the explanation of the injury more immediately done to these fruit trees. This anyone can take note of himself at the present season. When I was at first being troubled with this killing of the wood I painted the wires as a further preventive. This modified the injury, but it will not do to depend upon it entirely. Only a few seasons back one or two trees upon a wall by themselves escaped attention at this season. These when examined in the spring were affected in the same way as in years past. The same thing also occurs wherever any shoot perchance does come into contact with the wire in the case of the other trees. The wiring of walls, either perpendicularly or horizontally, for fruit trees or for flowers is, in my opinion, after years of close observation, a great mistake. It has been the cause of a deal of trouble when done in this fashion. The proper or rational method is to arrange for cross-wiring, for which purpose sections of wirework forming diamond shaped meshes are the best. In this way the current set up in the wire is modified or

diverted, and less harm is caused by it. In every instance the wire should be fixed close to the wall, so that there is not room for a cold current of air to play behind the trees. My wall is, unfortunately, wired at about an inch from its face. When a wall is not wired closely there is room for the fruits to get fixed in awkward positions. This I find will often occur through no fault of those in charge. In the case of Cherries the injury is not so serious; there it shows itself in gumming wherever the bark is injured. The moral, of course, is shack ties to some extent, but this will not always suffice, as I found out frequently in the case of the Peaches and Nectarines.—J. HUDSON.

* * * *We hope these remarks of Mr. Hudson will be considered by gardeners and many others who are so busy in wiring walls with galvanised and other ugly contrivances. Surely the proper way is to go back to the old thoroughly sound principle of laticing the wall with Chestnut, Oak, or—as they now come in such fine condition and are so cheap—Bamboos, which are wholly free from any objection, as far as we can see, and very much nicer to look at, whether on a house or garden wall. That we are going to do ourselves. We find that the complaints against galvanised wire, or wire of any kind, are as frequent in France as in England, and, therefore, both in the interests of fruit tree cultivation and also in those of the many beautiful climbers that we have for the adornment of the walls of houses, the whole of recent practice should be reconsidered.*—ED.

COVERING EARLY VINE BORDERS.

COVERING early Vine borders in autumn previous to starting the Vines is regarded by some as a waste of labour—their standpoint being that a foot or two of leaves applied at that season of the year cannot possibly communicate any heat to the roots—but the fact is that it is not maintained by those who practise it that heat is actually communicated by the covering, but that the heat which is already in the border is prevented from escaping, and snow and heavy cold rains prevented from exercising an evil influence. In one garden where ripe Grapes were expected in May, the border of the early viney was covered in October with from 18 inches to 2 feet of dry Oak and Beech leaves; common Flags, cut from a shallow pond some weeks before and laid on shed roofs to dry, being afterwards used as a thatch for the leaves. The house was elevated considerably above the ground level and entered by a couple of steps, the border outside being necessarily elevated as well. This, by the way, is my favourite form of early viney from a warmth point of view. The house was started in November, and when the border was pricked over with a five-tined fork as soon as the covering was removed in April, a multitude of fibrous roots was found immediately beneath the surface. In other two borders which never received any covering there were no roots worth mentioning nearer than a foot from the surface. Whenever a heavy fall of snow occurred it was not allowed to melt and sink into the leaves on the early border, but was immediately drawn off by a long-handled wooden scraper made especially for the purpose, and having a handle long enough to reach right across the border, this rendering treading on the thatch unnecessary. I remember that for some reason this viney was not started early one season, but allowed to come on gently, and the Vines which had been forced for twenty-five years in succession bore splendid exhibition bunches, plainly proving how well furnished with roots the border must have been. J. C.

Crab Apples in the garden.—I hope Mr. Parker's note in favour of the Dartmouth and other Crabs will lead to many more being planted this month. The scarlet and golden Siberian Crabs used to be much more planted than now, and it almost seems that with the introduction of John Downie, Maulai, &c., the common Siberian Crab had lost ground in our landscapes. Mr.

Lynch is rendering good service alike to horticulture and landscape gardening by growing a good collection of Crabs in one group in the botanic gardens at Cambridge. Should this meet his eye, perhaps he would be good enough to give your readers his impression of the best varieties for landscape effects, table, or room decoration. Few plants could enrich our lawns and home woods more than Crabs. The Fairy Apple, from which so much was expected some years since, is a chance seedling from the scarlet Cherry or Siberian Crab. It forms a welcome addition to any collection of Crabs, and is fairly good eating from December to April. It is best eaten with the rind on. The colour is a rich blend of crimson and gold, flesh deep yellow and juicy. It hardly equals for landscape effect the majority of the Crabs.—D. T. F.

Fig Brunswick.—At p. 357 Mr. Crook mentions a fine tree of this not always reliable open-air Fig he recently saw carrying a fine crop. For planting in a cool house Brunswick is a capital variety. I once had under my charge a good old tree growing on the back wall of a late vinery. The Vines only came up as far as the back pathway, thus allowing plenty of sun and light to reach the back wall. The fruit usually ripened in September, and did good service at an important show. On account of its vigorous habit of growth a limited root-run only should be allowed, abundance of rubble being mixed with the soil. I should think the tree mentioned by Mr. Crook is not an exception this season, as open-air Figs ought to have done fairly well, although they must have received a considerable check during the cold weather in May. When well grown the large Pear-shaped greenish purple fruit of Brunswick is hard to beat on the exhibition table.—C.

Blackberries as a paying crop.—The remarks by D. T. Fish (p. 358) on Blackberries as a paying crop are interesting at this season when such large quantities of extra fine well-ripened fruit are being sold in country towns. In East Anglia this autumn Blackberries have been most abundant and good, the great heat no doubt accounting in a measure for this. It is astonishing what heavy crops Brambles will yield where they have a free course, and intending planters would do well to provide means for the plants making a rambling growth. The finest crops of Blackberries I have ever seen have been about Rougham and Barton, two parishes a few miles from Bury St. Edmunds. Here many of the hedges are not trimmed, but allowed to grow for years. The Brambles climb to the top of these and the fruit hangs in dense clusters. It is a common thing to meet a party of Blackberry gatherers with buckets and baskets heaped up with fruit, being well paid for their trouble by, as D. T. Fish says, selling at 4d. a pound.—NORWICH.

Transplanting.—The recent rains, although yet insufficient to saturate the soil deeply, have sufficed to enable planting of most descriptions to proceed freely. Just as a wet soil is bad for planting, so, too, is a very dry one. But in its present condition, where the moisture just suffices to cause the soil to pulverise thoroughly, without being at all adhesive, then its condition for planting is of the best. Few things are of greater importance in transplanting than is lifting with exceeding care, so as to preserve all fibrous roots in their entirety. If the season be a favourable one and soil is in suitable condition, then transplanting of anything of reasonable dimensions furnishes little or no risk. When shrubs, fruit trees, Roses, &c., are obtained from a distance and arrive with roots somewhat dried, it is a good plan to soak the roots in water for a few hours before planting, as the wood is then well furnished with moisture. Very few things benefit by deep planting. It is quite in the nature of vegetation that roots should seek to go deep into the soil, and the cultivator, especially of fruits, finds ample labour in seeking to amend the habits of Nature by striving to keep them near the surface. When near the surface the roots can be artificially fed, thus enabling the plant, whatever it may be, to become either

more fruitful or more healthy, as may be desired. Shallow planting helps to that end, and, as all know, a mulch of long manure counteracts any dangers that may result from having the roots too near light and air. Not only is the soil sufficiently moist now, but it is yet fairly warm, and thus helps to the speedy formation of young roots.—A. D.

CURRENTS—RED AND WHITE.

Red and White Currants are in such great demand in their season (which lasts over many months) for tarts, jellies, and the many other ways in which they are used, that they must be largely grown in all private places. Commercially, I do not find them nearly such a paying crop as Black Currants or any other of the soft fruits. They, however, very rarely miss a crop, and if the profits of growing are

Currant White Dutch.

but small, they are tolerably certain, as prices fluctuate very little.

There is a great deal of confusion as to nomenclature, there being very many more names, especially among reds, than there are varieties, and it is high time that the authorities made a thorough examination of all that can be brought together and issued a reliable report on the subject. A very good selection of Red Currants for any garden would be Fay's Prolific, Raby Castle, and Reine Victoria; these are given in the order of their ripening and are the finest that can be grown in their seasons. Each of them is honoured with more than one name, but they should be readily obtainable under the names given. If confined to one, I would choose Raby Castle, which is a grand doer in every respect. A new and apparently distinct variety shown under the name of American Wonder is very fine indeed,

and though it may eventually turn out to be an old friend in new guise, its name should be included in any order given for bushes. Of whites, the old White Dutch is good and reliable, and White Transparent is a grand Currant, very sweet and useful for dessert or any other purpose.

For general purposes Red and White Currants are best grown vase-shaped on a clean stem; cutting out the centres admits light to the bushes and the fruit hangs better. They may be also trained cordon fashion, and are very useful for clothing walls facing north, where the fruits will hang for months in good condition provided the wall and bushes are kept clean. Cordons may be planted at any distance apart, according to the number of uprights to be trained on each tree. Bush trees are best at about 6 feet apart, and they should be planted on well-manured ground which must be free from all perennial weeds, especially those of a climbing nature, such as the wild Convolvulus, which can never be got rid of if once allowed to establish itself among the bushes. Mulching between the bushes is a great help during the growing season. Spur-pruning is the most convenient method of dealing with established bushes, cutting in each annual shoot to within an inch of its base, doing this at any time during autumn or winter. Summer pruning is also desirable, as by shortening the shoots about half their length just as the fruits commence to colour, a great deal of the Currant aphid is removed, light and air are admitted, and the bushes are better able to support the nets.

Propagate by cuttings in October or later, choosing strong straight growths cut with a heel of the older wood and to about 10 inches or 12 inches long. Disbud the lower portion to keep the stems clear of growths and put the cuttings in nursery rows, burying them to about half their length; see that the base of each cutting rests on the soil and make them firm. The soil in most garden nursery quarters is poor and the position often an unsuitable corner, neither of which is suitable for the Currant cuttings. These should have a good and well-cultivated soil from the first, as unless they get this they make weak shoots and weak bushes eventually. Train to a single stem the first year, then in autumn cut this back to the height of clear stem wanted. The after-treatment will consist in removing all but the necessary shoots, and the bushes may then be built up gradually by leaving a good length of ripened wood each year till the limit is reached. Currant bushes last a long time in good condition if well fed, and it is not unusual to see them twenty years old, but I like to keep up a succession of young bushes by planting a row every two years or so and destroying a similar number of the older ones. J. C. TALLACK.

Peach Bellegarde.—"J. C. T." has taken me to class Bellegarde with the lightest-coloured varieties. This was not exactly my meaning, though I must say that in at least a dozen years' experience of this finely-flavoured and useful late Peach I have never been able to get the colour in it that is described in nurserymen's catalogues and illustrated in works on fruit culture. The present year is no criterion, as the lack of colour in many fruits has been conspicuous, and my fruit of Bellegarde has when ripe been quite green, while fruit on the next tree to it—Waterloo—has been of very fair colour. I have no reason to doubt its being true, my trees having been obtained from a well-known firm who make fruit a speciality, yet I grew the individual trees for three years in the south of England, and brought them with me to Suffolk,

and have never seen a fruit of really high colour upon them. The soil in both cases has been heavy and not of the character to bring out the best points of Peaches.—H. R.

FRUIT AT THE NOVA SCOTIA PROVINCIAL EXHIBITION.

THE display at the recent provincial exhibition held in Halifax was in every way a credit to the growers, and in spite of all the insect and fungoid pests which every year invade the orchards, it is evident that our growers are each year improving on old methods and coming nearer to the ideal system. This year spraying has been far more general than ever before, and the result is that, notwithstanding the fact that the season was admirably suited to the growth of fungoid diseases, the Apples are far more free from black spot than usual. One of our largest Apple growers ventured the opinion that in future it would be impossible to grow exhibition fruit without spraying. The finest display at the exhibition was of course among the standard shipping sorts, such as Gravenstein, King, Ribston, Blenheim, Northern Spy and Baldwin, and the number of plates of show Apples of all these varieties was remarkable. There were twenty-five entries of Gravenstein, every one of which was a credit to the man who grew it, and as the Gravenstein is this year unusually well coloured, it made a fine sight. The Red Gravenstein, a sport from the true Gravenstein, was well represented, and seems to be gaining favour. Besides these old reliable varieties, a number of sorts comparatively new to Nova Scotia were shown. Two plates of Red Beitigheimer attracted much attention, and were by far the handsomest Apples in the exhibition. Their large size and brilliant red colour made them very attractive, but whether their quality is sufficiently good to warrant growers growing them may well be doubted. So long as buyers continue, as at present, to be guided in their purchases largely by the appearance of fruit, it is probable that this variety might prove very profitable, but there are indications that consumers are learning to consider other points than size and colour, and having already so many tried varieties which are known to grow to perfection in Nova Scotia, it is hardly probable that we would be justified in abandoning them for such new sorts as the Red Beitigheimer.

In "barrels packed for export" there were twenty entries, and if these may be taken as a standard of what the province is to furnish to foreign markets this year, our customers ought certainly to be satisfied. The bulk of Nova Scotia Apples goes to the London markets, though Liverpool receives a fair share, and this year an unusual number, more especially of Gravenstein, are going to the United States. Reports from all these markets indicate that the exhibition fruit was but a fair sample, and that the reputation of Nova Scotia Apples is not to suffer from this year's transactions.

The exhibits of Plums were fairly large, though, of course, Plums are of secondary importance as compared to Apples. Bradshaw, Pond's Seedling, Green Gage, Washington, and Burbank are the leading sorts. Moore's Arctic and Lombard, though largely grown, must give way before varieties of better quality. Burbank seems to be the most promising candidate for the future. Its large size, attractive appearance, and good quality make it sell at good prices and it bears transportation well, which is a consideration, for if Plum growing is ever

to become important here, some means must be devised to place our fruit on foreign markets.

Some very good samples of both Grapes and Peaches were exhibited, but Nova Scotia will never do more than supply her own markets with these fruits, and it is likely to be some years before she does even that.

Wolfville, Nova Scotia.

F. C. SEARS.

Apple Maltster.—This old midland variety is a favourite at Madresfield Court, where it does remarkably well and fruits freely. Whilst locally regarded as of excellent flavour, it certainly falls much below the flavour standard of our best dessert varieties. The fruits are of good size, larger than those of Ribston Pippin, though somewhat like them in shape, the flesh fairly soft, but soon becoming woolly—that is at least general experience. It is doubtless due to these defects that Maltster has not been widely grown. Another defect attributed to it is that the wood is so tender that entire trees have been killed during very severe winters. On that head more information is desirable, as, in any case, at Madresfield it seems to be as hardy as any other variety.—A. D.

Best flavoured Gages.—Were I asked to name the three best flavoured Gages I should say Transparent Gage, the old Green Gage, and McLaughlin's Gage. Transparent Gage is an awkward grower, forming its spurs a long distance from the wall, and, being also of rampant growth, is often slow in bearing unless in very poor soil, and even then generally needs root-pruning several times. The old Green Gage is perhaps the richest of the three and more appreciated for jam-making than any other Plum. McLaughlin's Gage is not so well known as it deserves to be, being a most delicious fruit, greenish yellow and heavily mottled. It needs less root-pruning than most of the Gages, young trees bearing freely. No Plum wall should be without these three varieties.—C.

Pear Fertility.—This Pear is largely grown for market in some counties, being a good cropper. I have never heard that fruit from orchard trees is liable to become suddenly soft and useless before it is fit for gathering. I had an espalier tree which bore plenty of fruit, but this invariably turned sleepy in the centre all at once. It was not that the fruit was left on the tree too long, but it turned from a comparatively hard, unripe state to a useless condition without the slightest warning. At last I rooted it out. The soil the tree grew in was of a light, warm nature; perhaps in a cooler, moist medium the fruit would have remained sound till gathered. Fertility, though not of the first quality, is nevertheless a good amateur's Pear. Where this premature decay does not affect it and in cold, bad Pear districts it might be grown as a garden tree.—C.

Grape sports.—How interesting would it be could we solve the physical problem involved in Grape sports. These are apparently of common occurrence, yet how few have come into commerce as permanent varieties. Cannon Hall Muscat, if really a sport product, is perhaps the best, but all the most popular Grapes seem to be of seed production. The sport from Muscat of Alexandria, which has been in evidence some three years at Chiswick, will perhaps prove when it fruits on its own roots to be a counterpart of the Cannon Hall variety. In any case we should soon be able to see whether as a sport it is worth general culture. A very fine Grape sport is that which Mr. Thomas Roelford has at Broxbourne, and which I have recently learned continues to show its very marked distinctness. Still, I do not learn that it has fruited on its own roots from eyes. This sport is on the Black Alicante, the berries having the thick skin of that variety, with berries the size of those of Gros Colman and rather oval in shape. It should make a fine late winter Grape. Another very fine sport, but from Gros Colman, can just now be seen at the Ashford Vineries, Cobham, Surrey, where a

Vine two years planted has in its upper portion so changed its character that the wood, so far from having the Gros Colman smoothness, is quite rough; the nodes or leaf-buds are very close, averaging six to the foot, as against three and four of the Gros Colman, and the leafage differs also. Two bunches have been produced of good size, but having abnormally large round berries that are double the size of those of the true Gros Colman bunches on the Vine. Here again, with every promise as now presented of a remarkably fine sport, nothing definite can be determined until young Vines taken from it have fruited. If such sports as those mentioned do not become permanent varieties then sports are worthless.—A. D.

APPLES FOR EXPOSED SITUATIONS.

MANY of the finest cooking and dessert Apples which succeed well enough in warm sheltered localities are next to useless in upland districts and cold situations. To plant them is only to court failure. One of the best Apples for such positions is Lady Heniker, it being of robust, hardy constitution, and though large, is of good dessert quality in December and January. In flavour it much resembles the Blenheim Pippin. The new and popular Apple Bismarck possesses a good constitution and bears freely in most seasons, quite young trees carrying fine, bronzy, handsome fruit. This is undoubtedly one of the most valuable additions to the list of really profitable Apples. Stirling Castle may be confidently planted in cold districts. A gentleman residing in Argyleshire informed me that it was one of the best varieties he grew. Seaton House is very similar to it, and a very worthy sort. The growth of Stirling Castle is short and stocky and gets well ripened each autumn. Keswick Codlin used to be recommended as a hardy, constant-bearing variety, but this is now superseded by that handsome Codlin, Lord Grosvenor. This variety crops so heavily on young trees that they are liable to be broken down by the weight of the fruit, especially in windy positions. Both the old and new Northern Greenings are excellent for cold soils and exposed places, the former keeping quite sound till March. Northern Dumpling, an October Apple of large size and handsome appearance, bears abundantly in cold northern localities, and should be specially noted by intending planters. Rosemary Russet, a dessert Apple of excellent quality, belongs to the same category. To the list must also be added James Grieve and Sturmer Pippin; the former succeeds where Cox's Orange is tender, and is of fine flavour, and the latter, owing to its close habit of growth, which protects the blossom in spring, carries a crop in nine seasons out of ten. In quality it approaches the Ribston, and will keep sound till April. The foregoing should all find a place in exposed orchards. J. C.

Pear trees casting their fruit.—There are a few useful good-flavoured Pears that unfortunately have a tendency to cast their fruits just as they have arrived at their full size and before they are fit for gathering. This is very annoying, as the fruit invariably shrivels and is useless. One of the worst in this respect is Knight's Monarch, a richly flavoured, useful-sized dessert variety in use for four months in winter. I fancy dropping is more common on light soils than in those of a stronger and more retentive nature, and this fact seems to point to the advisability of supplying the roots with a liberal amount of moisture, mulching also assisting the trees by preventing hasty evaporation. Comte de Flandre, a long, handsomely-shaped, free-bearing variety in season in November, has the same failing. I had a pillar tree on a west wall; the border sloped considerably, and in extra dry seasons the fruit dropped badly. Beurrd'Aremberg, one of the freest cropping and most useful December Pears in cultivation, is liable to cast its fruit, but it usually carries such a crop that there is sufficient fruit left. This Pear should be in

every collection, as it is almost equal to Winter Nelis in quality and remains in usable condition a considerable time. In my opinion the best, and, indeed, only way of reducing dropping to a minimum is by liberal mulching and several copious waterings during the swelling season.—
J. C.

TREES AND SHRUBS.

THE SEA BUCKTHORN.

(HIPPOPHAE RHAMNOIDES.)

DURING the autumn and winter months we have no more beautiful object among hardy vegetation than the Sea Buckthorn—certainly

for grouping, not only because the effect is so much finer, but also because it bears its male and female flowers on separate plants, and thus two at least of them are necessary for fruit to be obtained. But as the male plant possesses no attractive features beyond its foliage and habit, it is an economy of space to use in a group say six or ten female plants, whose flowers a single male plant will be found sufficient to fertilise. One can generally distinguish the male plant in its adult stage by its stronger habit and larger leaves, but I do not know any way of distinguishing young plants before they flower. If they are seedlings (and propagation by seed is the easiest method), they ought to remain in nursery

viz., *H. salicifolia*. This is a large shrub or small tree 20 feet high, with leaves much larger than our native species and not silvery. It does not appear to be of the same value under cultivation, fruiting but little and having less brightly coloured berries. Both species are, of course, absolutely hardy.

I have not heard of the fruits of the Sea Buckthorn being used in this country for food—the birds even leave them alone—but according to Brandis, in his book on the "Forest Flora of India," they are thus used by the natives of the Himalayas. He says: "In Lahoul, thickets of *Hippophae* are so valued as to be considered village property. The fruit is intensely acid, but boiled with sugar forms a

The Sea Buckthorn (Hippophae rhamnoides) by the lake in the Royal Gardens, Kew.

none that remains so bright for so long a time. Throughout those two seasons the younger branches (*i.e.*, the branches of the previous year) are thickly packed with brilliant orange-coloured fruits about the size of large Peas. The illustration shows a group of plants growing on the banks of the pond near the Palm house in the Royal Gardens, Kew. This group is very happily placed. Behind it is a dark mass of Bamboos, and on one side is the water, near enough for the roots to obtain the abundant moisture they love. The species is a native of Britain, and is most abundant on the east and south-east coasts, where it sometimes becomes a fair-sized tree. Apart from its fruit it is handsome in its graceful shoots and narrow silvery leaves. It is essentially a plant

quarters till the sex is determined, so that at the permanent planting no more than the necessary proportion of male plants need be set out. Where space does not admit of more, a single female plant could probably be made to bear fruit by grafting on it a shoot of the male.

Although the Sea Buckthorn gets to be a tree there is a specimen in the arboretum at Kew about 30 feet high whose trunk is 3 feet 6 inches in circumference at 3 feet from the ground—this need not deter anyone from growing it. It can be kept at any required size above 6 feet (the plants in the illustration do not average more), and pruning does not affect its fruitfulness.

There is another *Hippophae* in cultivation, a species from the outer and middle Himalayas,

palatable and wholesome preserve." In spite of its accommodating nature and its perfect hardiness, this shrub is greatly neglected by planters. This is the more remarkable because it is in its greatest beauty during that part of the year when it is most likely to be appreciated.

Kew.

W. J. BEAN.

Cratægus Lælandi in Finsbury Park.—Near the Manor House entrance to this park there are just now some very handsome bush specimens of this beautiful shrub. Mr. Melville, finding this impatient of removal, acquired a stock of young plants in pots, and these were planted out some two years ago. They are arranged in a broad border with a western aspect, some few feet apart from each other, and, being freely berried, the contrast with the dark green

foliage is most effective. A background of shrubs also adds to the effect of the bright red berries.—C. A. H.

PUBLIC GARDENS.

CHRYSANTHEMUMS IN THE PARKS.

BATTERSEA PARK.

THE collection of Chrysanthemums at Battersea Park is—like many others who have seen this season—somewhat under the average, owing no doubt to the very trying summer through which they had to pass. Judging by the attendance of visitors on the occasion of our call, there seems, however, to be no diminution in the public interest that the collection excites locally, and as a whole it is a very creditable and interesting display. The plants are housed in the same greenhouse as usual—a Palm house—but one not quite suitable for accommodating Chrysanthemums. The method of arrangement does not differ from that of previous years, there being a long sloping bank of plants with a path in front, the visitors entering at one end and passing along to the exit at the other end, so as to avoid any crowding or confusion.

Taking the old type of incurved first, it is worthy of note that most of the well-known popular sorts are represented, and, indeed, at most of the London County Council displays the older varieties, both in this and the Japanese section, seem to be freely used, and novelties in the general sense of the term must be looked for elsewhere. Abundant evidence of the value of many of the varieties discarded by exhibitors may be found at the parks, for many bright and effective blooms that are of no use on the show-board become positively radiant when judiciously intermingled in these long banks of colour, the tendency often being to run into varying shades of white and yellow. Baron Hirsch is rich and good in the incurved section, and its colour renders it of great value for these shows. Among other incurved kinds well known and needing no description, Empress (both white and golden), Mrs. W. Shipman, Golden Geo. Glenny, Lord Alcester, John Lambert, John Doughty, and Mrs. Robinson King are all well done and receive due recognition. Others, too, such as Prince of Wales, Jeanne d'Arc, Globe d'Or, C. H. Curtis, D. B. Crane, Mr. Bunn, Refulgens, Alfred Salter, John Salter, Lord Wolsley, and several others equally valuable, will show to what extent the section is represented, and the old lovers of the incurved blooms will not feel that the more modern Japanese has entirely extinguished what many people still consider to be the more perfect, if less showy, type.

Japanese, of course, figure very largely, and it is easy to imagine the necessity which compels the providers of such public displays as these to include a very large proportion of this protean flower in their collections, for, apart from questions of colour, diversity of form must be taken into account, and to this quality there really seems to be no limit with the Japanese. Old-time useful sorts include La Triomphante, pale pink; Lady Selborne, pure white, and its lilac-mauve parent, James Salter, very useful for an early opening show; Brise du Matin, dwarf, and of a pretty shade of pale lilac-pink, and one of Délaux's novelties of many years ago; the same raiser's October variety, M. William Holmes, crimson and bronze; and his Hamlet, delicious soft salmon-rose, has hardly been bettered for beauty of colour, and the same remark will apply to his Comte Lurani, which was figured in THE GARDEN soon after its merits were first appreciated. Unfortunately for himself, M. Délaux has not kept up his standard, for another of his, Charlotte de Montcabrier, is a very graceful, long-petalled drooping Japanese, colour delicate pale pink. His M. Freeman, deep pink, very dwarf, is useful for a front row pot plant, and his darker Jeanne Délaux is still preserved for colour, which is an intense dark

velvety crimson with golden reverse. Japanese from other sources include in crimsons Wm. Seward and John Shrimpton; in whites, Lady Byron, Mlle. Lucroix, Mrs. H. Weeks, and in other shades there are G. C. Schwahe, very bright and fine; Sunflower, good; Val d'Andorre; the old purple-maroon Edouard Audignier, Edith Tabor, very fine in form and of a beautiful shade of pure yellow, and Lady Hanham, the salmon-rose and gold sport from Viviani Morel, which is really one of the most delicate and finely formed flowers wherever we have seen it this year.

Calvat's seedlings are not quite so freely grown in the parks as in the trade collections, but they no doubt will be in the course of time. Of these, M. C. Molin (golden-bronze) and President Borel are everywhere; Mme. Ed. Rey, a fine big flower, colour pale pink; Louise, pale pearly pink, big and globular; M. Chenon de Leché, Mlle. Thérèse Rey, white; Mme. Carnot, white; Australian Gold, pale yellow; and l'Ami Etienne, pale pink, are universally admired, and as many of this raiser's blooms are somewhat early, it seems to give him rather an advantage over his rivals in this respect.

American kinds, however, still strive for a fair share of public recognition, and of these there are at Battersea in good form such standard sorts as H. H. Fowkes, medium size, but clear in colour; W. Tricker, very pretty bright pink; Gloriosum, an old well-known yellow; G. W. Childs, deep bright velvety crimson and gold; Puritan, Eda Prass, W. H. Lincoln, the newer and deep golden-yellow Modesto, and Good Gracious.

The hairy section and a few of the Anemone type are also represented, and of the former we specially noted one plant of the once-famous Mrs. Alpheus Hardy, Esau, bright pretty pink; Mrs. Dr. Ward, Spatel, deep pinkish lilac; Hairy Wonder, a shiny, glistening golden-bronze; Beauty of Truro, &c. Free use is made of some lush-grown plants of Margot, a pretty decorative Japanese, and the beautiful little pompon Mlle. Elise Jordan. Other decorative plants of pompon varieties, such as Sunset, Sœur Melanie, La Vogue Précocité, Rosinante, and Golden Mme. Marthe are effectively and tastefully arranged.

WATERLOW PARK.

In this popular North London park the Chrysanthemum is represented in fine form this season. A few sorts, as Mme. Carnot and William Tricker, with their respective sports, have failed to come well from an early bud selection, the hot weather prevailing during August accounting for this. One specially noticeable feature of the display is the bright and striking colours of the flowers, the crimson-coloured blossoms being wonderfully brilliant, and as these are grown somewhat freely here, contrasts of crimson and yellow, white and crimson, besides many other pleasing effects, were produced throughout the long range of disused vineries and other glass structures. Some 2700 plants in 275 varieties will at once give an idea of the representative character of the display, and considerable taste has been evinced in the effective grouping of the different types of the flower. While the Japanese varieties predominate, there is also a goodly sprinkling of Anemone, incurved and decorative sorts, and not the least pleasing feature of this interesting exhibition is the free display of pompons. The best of the old sorts and a useful number of novelties make the show of more than ordinary interest, as this enables the public who throng the houses during the hours of opening to make comparisons. Of the older Japanese sorts represented in better form than usual we noticed Gloire du Roeder, quite orange-crimson in colour and carrying handsome flowers; Mrs. E. G. Hill, large pale blush-pink; Prefet Robert, as good as we have ever seen it; A. H. Neve, still considered a lovely bloom; and Mrs. W. H. Lees, a rose-tinted white flower. Eda Prass, pale creamy pink, on first crown buds from plants stopped in March last, was most effective. Avalanche, the popular white of a few years since, was developing chaste blossoms of large size, and

is rightly held in high esteem here. William Seward and G. W. Childs, respectively deep and bright crimson, were represented in capital form and colour; while Viviani Morel and its sports, on both early and late bud selections, were coming very full, although the later flowers were much prettier and possessed good colour.

New Japanese kinds dotted here and there were Pride of Exmouth, pleasing only in late flowers, although very large; G. J. Warren (yellow Mme. Carnot) on late buds was opening kindly; Emily Silsbury, a plant of easy growth, with lovely rich creamy white blossoms, was often in evidence. Lady Byron, very fine white; Duchess of Wellington, large spreading yellow; Australian Gold, pale canary yellow; Phœbus, good in many different stages; James Bideneope and Modesto, the latter one of the best deep rich yellows, were also very fine. Incurved sorts were represented by Rena Dula, but coming somewhat rough, a later bud selection evidently suiting it better. Baron Hirsch in fine bold, globular flowers of rich cinnamon-bud, and the different members of the Rundle family, viz., Mrs. Geo. Rundle, Mr. George Glenny, and the rich yellow Mrs. Dixon were also well represented. Pompons of good and pleasing form and colour were William Westlake, the best of the yellows; H. H. Crane, crimson, tipped gold; President, still highly thought of; Mme. Marthe and Golden Mme. Marthe, Black Douglas, devoid of coarseness, and a pretty little rose pompon Anemone named Emily Rowbottom, and wonderfully free. In the open borders early-flowering varieties are very freely used, and at the time of our visit were very effective in the open borders.

SOUTHWARK PARK.

The T-shaped greenhouse near the Gomm Road entrance to Southwark Park is just now in a full blaze of colour, for the Chrysanthemum exhibition is in full swing, and the dwellers in this crowded locality highly appreciate the floral treat that is annually provided for them by the London County Council. The shows in the parks are very different from those provided by the trade importers and the ordinary societies' exhibitions, inasmuch as they make no pretence to be collections of all the latest novelties, but are composed principally of good old useful varieties which are best adapted to the requirements of the locality. The collection at Southwark shows signs of considerable taste in its arrangement, there being a central bank of plants with a winding path all round the greenhouse and a side border of plants, which allows a free circulation of the numerous visitors. Interspersed at intervals are various fine-foliaged plants, such as Palms, Ferns, Araucarias, Ficus elastica, Dracenas and the like, which are more effectively and freely used than at some of the other public displays, and transform the glass structure into a veritable winter garden.

Very attractive are the deep purple plum-coloured blooms of Pride of Madford, a big, solid-looking novelty of Australian parentage. Descartes, a rich wine-coloured Japanese Anemone, is freely used and is bright and useful for the purpose. Charles Davis, Mrs. J. Shrimpton, deep golden bronze; Oceana, also a colonial of deep golden yellow; the old white Fair Maid of Guernsey, J. H. Runciman, also a deep rich tone of golden yellow and finely incurving; Mme. C. Audiguier, Phœbus, Miss Ethel Addison, big and solid and of a rich purple-mauve; and the gigantic Australie, similar in form, but rather duller in colour, are all of sufficient merit to attract attention. Varieties of continental origin in the Japanese section comprise such valuable flowers as Gloire de Mezin, a fine globular golden bronze of deep tone and early; M. Demay Tallandier, dark crimson and gold; Commandant Blusset, purple amaranth, with a silvery reverse; Prefet Robert, somewhat similar in colour, but with a deeper and bolder petal. One of the most striking and effective varieties from this source is Gambetta, which is a beautiful shade of golden reddish terra-cotta, with reverse of old gold. A very delicate shade of pale pink is to be found in Charlotte de Mont

cabrier, and somewhat deeper and broader in the floret is the good old useful *La Triomphante*, one of De Reydellet's seedlings that seems to be a great favourite at all the County Council displays. Vivian Morel, M. C. Molin, M. Georges Biron, Mme. Carnot, M. Pankoucke, the very effective golden bronze *Source d'Or*, and the deep rosy pink N.C.S. Jubilee make up the list of the best of the continentals. American seedlings come in for a fair share of recognition. G. W. Childs, the well-known crimson, is always effective in a mixed group, and the tall but delicate soft pink Mrs. E. G. Hill is usefully employed as one of the back row plants for an early display. *Gloriosum* (yellow), *Interocan*, W. Tricker, *Puritan*, &c., are the best from the other side of the Atlantic.

Still confining our remarks to the Japanese section, home raisers are represented by W. Seward, *Gloire du Rocher* in crimsons, while the best yellows comprise *Marjory Kinder*, *Edith Tabor*, M. C. E. Shea, the pure pale yellow sport from Mlle. Lacroix, *Sunflower*, H. Shoemsmith and others. Whites may be found in good examples of *Lady Byron*, *Emily Silsbury*, *Mutual Friend*, *Mrs. C. Blick*, *Elaine*, *Lady Selborne* and a few others. Incurved kinds are grown, and several good blooms of C. H. Curtis, *Baron Hirsch*, and M. R. Bahuant are open. The *Queens*, *Rundles*, *Beverleys*, D. B. Crane, *Lord Wolseley* and *Prince Alfred* are among the best in this group.

Hairy varieties, which are always useful for such displays, are not so numerous here as they were a few years ago, but in one corner of the greenhouse *Enfant des Deux Mondes* (white), *Esau* (rosy pink), *Dr. Ward* (yellow), *Mrs. W. H. Caldwell* (yellow), *Louis Boehmer*, *Prima Donna*, *Sautel 1893*, *F. Bertin* and *King of the Hirsutes* are grouped together.

An open space for Preston.—A unique gift to their operatives is about to be made by Messrs. Horrocks, Crewdson and Co., manufacturers, of Preston and Bolton. At the former town they have purchased for £5000 the Militia barracks and some private ground in Stanley Street containing 10,776 square yards, with the intention of converting the place into a recreation ground for their employes. The proposal was mentioned at a meeting of the Lancashire County Council, from whom the premises have been bought, and it was heartily commended.

The extension of Hampstead Heath.—Proposed early opening.—The full amount of £41,000 required by the committee for the acquisition of the Golder's Hill estate adjoining Hampstead Heath, as a public park, having been raised or promised, the committee hope to open the park before Christmas, without waiting for the London County Council to obtain the necessary Parliamentary powers to take it over. The committee is therefore negotiating with the County Council for the opening of the new park under the joint control of the committee and the Council, until such time as the Council may legally take it over.

Open spaces.—At the monthly meeting of the Metropolitan Public Gardens Association, 83, Lancaster Gate, the Earl of Meath, chairman, presiding, it was announced that the £41,000 required for the acquisition of the Golder's Hill estate as an addition to Hampstead Heath had been completed. It was reported that the association had commenced the laying out of the Paragon, New Kent Road, that Albion Square Garden would soon be completed, and that it was hoped shortly to take in hand Christ Church Churchyard, Blackfriars Road, and a similar ground at Plaistow. It was decided, in response to applications from local authorities, to plant trees in certain thoroughfares in Clerkenwell, Islington, and Shoreditch, and to grant some apparatus for a gymnasium in Whitechapel.

The weather in West Herts.—Another very warm week for the time of year, and the third in succession. Throughout this period there has not

occurred a single unseasonably cold day and but two cold nights, when the exposed thermometer on each occasion indicated 6° of frost. The ground is at the present time about 4° warmer than the November average both at 1 foot and 2 feet deep. Rain fell on the first two days of the week to the total depth of nearly half an inch, but none at all has since fallen. The winds were, as a rule, light, and came mostly from some southerly or westerly point of the compass. During the three days ending the 6th the sun shone brightly on an average for 5½ hours a day, but throughout the rest of the week there was a very poor record.—E. M., *Berkhamstead*.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 8.

THE meeting of Tuesday last was a thin one compared with those recently held. A grand exhibit of Orchids, quite unique in the numbers of hybrid *Lælio-Cattleyas*, &c., came from Messrs. Veitch's collection, the gold medal being most deservedly awarded. The same award also was made to dessert Apples from Messrs. Bunyard and Co., highly-finished fruits being staged.

Orchid Committee.

Awards of merit were given to the following:—

CATLEYA BOWRINGIANA LADY WIGAN.—This is a very distinct variety, the sepals and petals of fine form and substance, delicate lilac in colour. The front lobe of the lip is lilac, suffused with rose, the centre having a broad band of deep purple, which extends well into the side lobes, forming a striking contrast to the creamy white of the throat. Two cut racemes came from Sir F. Wigan, Clare Lawn, East Sheen.

CYPRIPEDIUM WOTTONI (*C. bellatulum* × *C. callosum*).—This is a distinct and beautiful hybrid, the broad dorsal sepal partaking in shape of the characters of *C. callosum*, the upper margin white, suffused with rich purple, with some green towards the base, the whole heavily veined with dark crimson-purple. The petals are rose-purple, margined with white at the apex, with numerous small brown spots on the lower half. The lip is rich purple, veined with a darker shade, the large disc of the column rich purple, shading to green in the centre. From Mr. R. I. Measures, Cambridge Lodge, Flodden Road, Camberwell.

Messrs. J. Veitch and Sons sent a large and interesting group, consisting principally of *Cattleya* hybrids. The most prominent among these was *Lælio-Cattleya callistoglossa ignescens*, the sepals and petals pale lilac, the whole of the front lobe of the lip crimson-purple, margined with pink. It has the characteristics of *C. Warszewiczii* in the yellow eyes at the base of the lip. In *L. C. Dæcia* the sepals and petals are deep rose, mottled with white, the lip rich velvety crimson, veined with numerous small yellow lines at the base. *L. C. Statteriana* varies considerably, but all the forms have the intermediate characteristics of the two parents. In *L. C. Lady Rothschild* (*Lælia Perrini* × *Cattleya Warszewiczii*) the sepals and petals are larger than in the other *Perrini* hybrids, the lip purple, margined with white, with a large creamy white disc at the base. *Cattleya Mantini* (*C. Bowringiana* × *C. Dowiana*) has rich purple sepals and petals, the lip crimson-purple, with numerous yellow veins through the throat. *C. Bowringiana*, *C. labiata*, *C. Dowiana* and other species were well represented. Among the numerous *Cypripediums* were the yellow *C. Lawrenceanum* *Hyeatum*, two fine plants of *C. insigne* *Sanderæ*, and fine specimens of *C. Charlesworthii*. The hybrids were represented by fine forms of *C. Arthurianum* and the thickly-spotted *C. A. pulchellum*. In *C. Euryales* (*C. Boxalli* × *C. Lee-annum*) the dorsal sepal is white, suffused with rose, and thickly covered with large rich purple spots, the base green, with numerous

large blotches, the petals pale green, suffused with brown, the lip brown in front, shading to green. *C. Actæus* (*C. Leeannum* × *C. insigne* *Sanderæ*) has the dorsal sepal white at the top, shading to green at the base, the petals yellow, spotted and lined with brown, the lip broad, deep yellow, veined with green. *Masdevallias* were represented by *M. Imogene* (*M. Veitchii* × *M. Schlimi*), in which the ground colour of the flower is yellow, heavily suffused with rich crimson. *M. Ajax* has the intermediate characters of the two parents, both in colour and shape. The *Oncidium*s were well represented in such varieties as *O. varicosum*, *O. Forbesi*, *O. dasystyle*, and *O. spillopterum*. *Dendrobium atroviolaceum*, with two spikes of its yellow and purple flowers, was also shown. A plant of *Miltonia Bleuana* with seven flowers on the raceme, *Brassias*, *Odontoglossums*, *Vandas*, and other interesting species were also well represented. A gold medal was awarded. Messrs. F. Sander and Co. sent *Cypridium Jensenianum* (*C. hirsutissimum* × *C. vexillarium*), a pretty form of *Cymbidium Tracyanum*, and *Angreecum polystachys*. In *Dendrobium chloropterum*, a New Guinea species, the sepals and petals are green, suffused and veined with dark purple in the centre, the side lobes veined with purple.

Mr. James Douglas, Edenside, Great Bookham, was awarded a bronze Banksian medal for a cut collection of *Cattleya labiata*, the flowers fine in substance and in colour. Mr. J. Bradshaw, The Grange, Southgate, was awarded a silver Banksian medal for a useful and interesting group of hybrids and species of the *Cattleya* family. The most prominent of these was *Cattleya Mantini*, the flowers unusually dark and good in substance. A dark form of *C. labiata* was in striking contrast to *C. labiata grata*, the sepals and petals of which were almost white, the lip having a slight suffusion of rose on the front lobe. *C. labiata Etona* has pure white flowers, except the centre of the lip, which is crimson-purple with some yellow at the base, and brown lines through the throat. *Lælio-Cattleya Statteriana* and *L. C. Dæcia* were also well represented. The Rt. Hon. J. Chamberlain was awarded a silver Banksian medal for a collection of hybrid *Cattleyas* and *Dendrobium Phalenopsis*. Prominent among these was *Cattleya Mrs. Endicott*, having the intermediate characters of the parents in the sepals and petals, the lip having the purple lines as seen in *C. maxima*. In *Lælio-Cattleya Semiramis* (*Lælia Perrini* × *Cattleya Gaskelliana*) the sepals and petals are deep rose, the lip open, crimson-purple in front, with some white and yellow markings at the base. *L. C. Sallieni* and *C. Fausta* delicata were also included. Mr. H. F. Simonds, Woodthorpe, Beckenham, sent a large group, consisting principally of *Cattleya labiata*. *Odontoglossum grande* (finely flowered), a good variety of *Lycaste Skinneri* *alba*, *Masdevallia tovarensis*, numerous *Oncidium*s, and *Cypridium*s in variety. A silver Banksian medal was awarded. Sir William Marriott sent *Sophr. Lælia Marriotti* (*Lælia flava* × *Sophr. grandiflora*). The combination of the two species in this hybrid is wonderfully blended in the flowers. The shape is that of *Sophr. grandiflora*, the sepals and petals yellow, streaked slightly with orange-red, the front lobe of the lip yellow, suffused with brown. Mr. J. T. Bennett-Pöe sent a cut spike with fine flowers of the true *Vanda insignis* of Blumé, and the Earl of Lisburne showed a pretty form of *Cattleya labiata*.

Floral Committee.

A first-class certificate was awarded to

POLYPODIUM GRANDE NIGRESCENS.—This was stated to be a hybrid, having *P. nigrescens* and *P. vulgare grandiceps* for its parents. The plant greatly favoured *P. nigrescens* in the colour and somewhat in the formation and general character of the fronds, more particularly in the raised nipple-like excrescences produced by the fruiting spores. Of the participation of *P. vulgare grandiceps* in the production of this plant there was no apparent evidence, and even the heavy tassel for-

mation at the extremities of the larger fronds served but to indicate a possible or probable development of the typical *P. nigrescens*. From Messrs. Jas. Veitch and Sons, Chelsea.

The following received awards of merit:—

BEGONIA WINTER PERFECTION.—A semi-double rose-coloured flower, a cross between a fibrous-rooted and a tuberous-rooted variety. It bears an abundance of well-developed flowers and is of good habit. From Messrs. Jas. Veitch and Sons.

DRACENA THE SIRDAR.—This is of very compact and dwarf habit, the broad, handsome foliage of a dark green and bordered with crimson-scarlet, the younger heart shaped leaves of a brighter shade. From Messrs. Veitch and Sons, Chelsea.

NERINE LADY CLEMENTINE MITFORD.—A very pleasing form, with flowers of a soft delicate salmon shade, the perianth divisions beautifully undulated and forming a perfect head of bloom. From Mr. H. J. Elwes, Andoversford, Gloucester (gardener, Mr. Lane).

NERINE MISS JEYKILL.—In this the form of the divisions is but slightly undulated, the head of blossoms, as also the individual flowers, of large size, and the colour a clear rose-salmon. From Mr. H. J. Elwes.

NERINE MRS. DOUGLAS.—In this the flowers are more distinctly bell-shaped and without the recurving or wavy segments of the kinds previously named, the colour being a rosy cerise, with pink shade. From Mr. H. J. Elwes.

CHRYSANTHEMUM LORD CROMER.—This is one of the handsomest flowers of the year, happily, too, an English-raised seedling. The colour is the richest crimson-scarlet, with velvet pile-like lustre, and the pale golden tipped florets that incurve to the centre complete a very finely developed bloom. The petals are broad and finely proportioned. From Mr. Robert Owen, Castle Hill, Maidenhead.

CHRYSANTHEMUM MR. W. MEASE.—This is a finely-formed Japanese flower with drooping florets of great length, the flowers of splendid proportions and of the largest exhibition size, the colour a delicate creamy white. From Mr. Robert Owen, Maidenhead.

CHRYSANTHEMUM JAMES MOLYNEUX.—A finely-formed Japanese of the purest white, flowers very large and florets long and drooping. From Mr. J. C. Garnier, Rookesbury Park, Farnham (gardener, Mr. N. Molyneux).

CHRYSANTHEMUM PRESIDENT BEVAN.—A Japanese incurved of large size, though somewhat variable as seen in two collections. In one flower the shade was a delicate rose-bronze, flushed with gold; in another bloom a flesh tint prevailed. It is, however, a handsome flower and finely formed. From Mr. Wells, Redhill, and Mr. Godfrey, Exmouth, Devon.

CHRYSANTHEMUM JOHN POCKETT.—A splendidly formed, broad-petalled flower of crimson and gold, the former, of a very rich and beautiful shade, predominating. From Mr. W. Wells.

CHRYSANTHEMUM NELLIE POCKETT.—A finely-built flower, in which the florets are very numerous and make up a bloom of rare fulness. The colour is creamy white. From Mr. W. Wells.

Among the most interesting groups at this meeting was the batch of hybrid Nerines from Mr. H. J. Elwes. As the majority were under number it is difficult to particularise, and, indeed, had it been otherwise, the difficulty had been equally great where all are so good. It is very evident that Mr. Elwes is developing the genus with a will, and that in the hosts of seedlings yet unflowered there may be many of great beauty, surpassing even the lovely things we have seen. The colours consist of shades of salmon, rose, cerise, pink, scarlet, &c. Apart from the colour there is a pleasing variety of form both in the bell-shaped section and in those whose petals recurve, and possess also a prettily undulated surface. A capital pot of *N. excellens* (*O'Brieni* × *flexuosa*) carried some fifteen or so of its pretty rose-carmine heads and was very attractive. In all there were shown some five or six dozen pots of these pleasing autumn flowers,

which in their setting of *Pteris tremula* gave a very good result, the group being awarded a silver-gilt Flora medal. From Mr. H. B. May, Edmonton, came a very instructive exhibit of Polypodiums, representing some fifty species and varieties of these easily grown greenhouse Ferns. One very useful lesson to be gathered from these complete exhibits of Fern genera which Mr. May has of late taken in hand is that visitors may readily compare them and note the relative merits of the distinct forms, as also the varying types which are contained in so diversified a group. One very notable example was *P. nigrescens*, a plant of rather spreading habit and with, so to speak, branched fronds. In this species the fruiting spores are so formed as to produce a nipple-like excrescence on the upper surface of the leaves, in some instances elongated and in others perfectly rounded, and generally nearly the eighth of an inch in depth. It is a very remarkable characteristic in this species, and provides a striking and picturesque feature. Other noteworthy kinds were *P. plumosum*, *P. crassifolium*, almost Scolopendrium-like in the form of its fronds, which are fully 2 feet long; *P. angustatum*, very glossy; *P. Schneideri*, which may be described as a glorified form of the Welsh Polypody (*P. cambricum*); *P. decurrens*, spreading and very curiously branched; *P. iridoides*, *P. phyllitides*, *P. musciforme*, the last three possessing more or less the same typical features, and forming a very useful and hardy enduring race of plants. At one end were some splendid examples of *Begonia Gloire de Lorraine*, model bushes grown from cuttings inserted but six months ago, and now complete masses of blossom (silver-gilt Flora medal). Mr. W. Wells, Earlswood, Redhill, staged a somewhat comprehensive group of Chrysanthemums, the boards of large blooms being relieved at intervals by vases of free-growing decorative kinds in abundance. In the latter, *Crimson Pride* and *Mytchett Beauty*, of a pleasing yellow shade, were noticeable. Among the large blooms, *Mrs. White-Popham*, white, lined with red; *Lord Ludlow*, a grand yellow; *The Convention*, clear bronzy gold; *Mr. T. Carrington*, purple and silvery mauve; *Leocadie Gentils*, one of the most distinct of the hairy tribe; *Mrs. J. W. Barker*, gold and bronze; and a profusion of *Nellie Brown*, the sport from *Ryecroft Glory*, were noteworthy (silver Flora medal). Mr. T. S. Ware, Tottenham, had for the time of year a remarkable exhibit of Dahlias, flowers of such quality as is not available one year in a dozen on the 8th day of November. In the *Cactus* group there were such things as *Fusilier*, *Leonora*, *Cycle*, *Dr. Jameson*, *African*, very dark; *Iona*, *terra-cotta*; *Beatrice*, *Ensign*, *Lady Penzance*, fine yellow; *John H. Roach*, yellow; *Mrs. Wilson Noble*, *Mrs. Beck*, *Harry Stredwick*, crimson, and others equally good. These were supported on either side by an equally good lot of hybrid pompons in leading sorts, and backed with single-flowered Chrysanthemums in bush form in pots (silver Flora medal). Mr. N. Molyneux, gardener to Mr. J. C. Garnier, Fareham, had several novelties among Chrysanthemums, such as *Nellie S. Threlfall*, a fine white incurved, and *John Miles*, a nicely formed flower of a bronzy yellow shade. From *Forde Abbey* Mr. J. Crook, gardener to Mr. W. H. Evans, sent a beautiful box of unnamed double Violets, which displayed good culture. In such cases, however, a certain interest ever attaches to the name of the variety. A grand basket of a white zonal *Pelargonium*, specially grown for winter blooming, and called *White Abbey*, came from Messrs. Geo. Bunyard and Co., Maidstone, the plants being splendidly flowered. Several masses of perennial *Asters* came from Messrs. Veitch and Sons, such as *A. grandiflorus* and *A. Tradescanti*, being very good, the latter example being some 6 feet through and quite enveloped in pure white blossoms. Mr. Robert Owen, Maidenhead, had a few of his Chrysanthemum novelties, such as *Owen's Memorial*, *Edith Owen*, rosy mauve, very fine, and *Mrs. W. C. Egan*, a clear lilac-rose, being among the best. Mr. Godfrey, Exmouth, likewise had a few boards

of good blooms, including *Lord Boston*, *Mrs. J. G. Glessmer*, clear gold; *Autumn Glory*, a clear pinkish mauve; and *Le Grand Dragon*, a fine golden that appears everywhere good this year. *Dome d'Or* is all the name implies, and equally so *King of the Yellows*, a rather small flower, but possessing a shade very near the old *Jardin des Plantes*. Mr. Sander, St. Albans, had finely-grown plants of *Acalypha hispida* and *A. Godselliana*, while the two *Dracenas* bearing the above varietal names were also included in the exhibit.

Fruit Committee.

This committee had fewer exhibits than usual; indeed, there was only one collection of fruit. This came from Messrs. Bunyard and Co., Maidstone, and consisted of 100 dishes of dessert Apples, remarkable for their splendid finish and beautiful colour. The central group was the new *Allington Pippin*, not unlike a *Cox's Orange*, but brighter in colour. *Jas. Grieve* was also very fine. This promises to be a valuable addition to the dessert varieties and is a favourite in Scotland. Few Apples, as regards symmetry, can compare with *Mabbet's Pearmain*. A new Apple was called *Lodddington Pearmain*. This is not by any means a good name, as it will clash with *Lodddington Seedling*, a very different fruit. Another less known but beautiful Apple is *Christmas Pearmain*. Most of the *Calvilles* were represented, and we have never seen better *Russets*. The *Egremont* and *St. Edmunds* were beautiful fruits. *Winter Ribston* was a splendid lot. This fruit is outwardly too like *Blenheim Orange* to attract notice, but the flesh is quite distinct. It is an excellent but little-known Apple and a good bearer. Many of the older varieties were remarkable for their colour, and the collection well deserved the gold medal awarded. *Pear Beurré Clairgeau* was sent by Messrs. Jones and Son, Shrewsbury, these being fruits from a second lot of flowers. A seedling Apple named *Giscoinne's Scarlet Seedling* was also sent. This is a pretty Apple, which the committee desired to be sent on another occasion to test keeping qualities. A very bright crimson Apple, a seedling from *Devonshire Quarrenden*, not unlike *Sops of Wine*, with the colour permeating the flesh, came from Messrs. Garden, Northampton. An excellent dish of *Plum Coe's Golden Drop* was sent by Mr. Vert, Audley End Gardens, Saffron Walden. The same exhibitor also sent a good seedling *Cucumber* named *Vert's Favourite*. From Mr. J. Day, Galloway House Gardens, Garliestown, N.B., was sent a nice dish of *James Grieve Apple*. This was considered a good addition to the dessert varieties.

Vegetables were not at all well represented. There was a nice lot of *Every Day Cucumber* from Messrs. Sutton and Sons, Reading. This is a nice shapely fruit, very much resembling *Lockie's Perfection*. From Mr. W. Bygrave, The Gardens, Rouse Lench Court, Evesham, came a nice dish of *Peas* named *Charles I.* Unfortunately, the sender gave no particulars as to height. It was sown early in July. *Potatoes* came from two sources; one to show the cooking qualities, as it becomes black when cooked. This was referred to the scientific committee. Doubtless the soil lacked lime. A nice lot of *Tree Tomato* (*Cyphomandra betacea*) came from the Royal Gardens, Kew, but we certainly cannot say much for the flavour. The fruits were gathered from a plant 10 feet high, and growing in a warm house.

The National Chrysanthemum Society's show.—Owing to pressure on our space we have been compelled to hold over the report of the show at the Aquarium till next week.

Gardeners' Royal Benevolent Institution.—We are asked to state that the offices of the above institution have been removed from 50, Parliament Street, to 175, Victoria Street, S.W.

Endurance of Bamboo stakes out of doors.—In reply to "E. T. L." (p. 380), Bambo

stakes are far better than those of any native wood for endurance. I have used them largely in positions where a good deal of moisture is required, such as for Chrysanthemums, either in pots or planted out, and where stakes of any other kind are of very little service after one year. The Bamboos, if taken care of, will last for several years, and although somewhat more expensive at first, are very much the cheaper in the end.—*J. G., Gosport.*

NOTES OF THE WEEK.

Chrysanthemum King of the Yellows is not a large flower, but possesses a very good shade of yellow, which is an approach to the old and well-known *Jardin des Plantes*, one of the finest golden kinds ever raised, but, unfortunately, a poor grower.

Cyclamen neapolitanum and its variety album still provide a pretty display of flowers, the effect of which is enhanced by the beautiful foliage that spreads far and near from the strong corms of this plant. For its foliage alone the plant is worth attention.

Abelia uniflora.—This very pretty flowering shrub still continues to produce numbers of its white, flesh-tinted blossoms. It is a capital plant for affording a covering to a warm wall, the growth being somewhat free and dense, and therefore forming a good covering, irrespective of its abundant and profuse flowering for many weeks in succession.

Cedrus Deodara.—I send you a photo of a tree in the grounds here. It has been planted about sixty years, and is growing in a strong loamy soil. It is 50 feet high, the circumference being 90 feet, and is very symmetrical and well furnished to the ground. Pines grow very luxuriantly here.—*T. B. FIELD, The Gardens, Ashwellthorpe Hall, Norwich.*

Bouvardia jasminoides.—This is one of the most beautiful of the genus and certainly deserving of very extensive cultivation. The purity of the blossoms, as much as their pleasing fragrance, is ever admired, and in any choice floral arrangement the sprays of pure white display themselves to advantage. The variety, too, is of fairly easy culture, and by rooting batches of cuttings in succession from January to the end of April a capital succession of its flowers may be secured during the autumn and winter ensuing.

Colchicum autumnale roseum plenum.—Under this lengthy name I have a pretty Meadow Saffron, which is later in bloom than any others in my collection. I have it in two positions, and when others close to it are quite over, this variety still gives a profusion of its rose-coloured double flowers. To day (November 7) a small clump looks quite bright, despite the heavy rains which have of late been so destructive to the *Colchicums* and *Crocuses*.—*S. ARNOTT, Carsethorn, by Dumfries, N.B.*

Chrysanthemum Lord Cromer.—Among new Chrysanthemums this variety promises to excel. Indeed, it is by reason of its colour quite unique. In point of colour the predominant shade is crimson-scarlet. It is, however, of such a remarkable hue as to give more the idea of vermilion, lightly clouded with crimson, which produces a wondrous light on the surface of the florets. It is one of Mr. Robert Owen's seedlings, and certainly a handsome flower, not one of those monsters that come by cultural excesses.

Aster Tradescanti.—For producing a display of blossoms this is perhaps one of the freest of all the Starworts. It is one of those kinds not suited to the border nearly so well as to isolated positions, by reason of its spreading habit. On the grass such a plant would be very beautiful in effect just now. Indeed, not a few of these things would be very pretty so placed, more so if given a rigid selection of kinds with good treatment. Of course, there are hosts of weeds in the garden that we cannot by any means ignore.

White zonal Pelargoniums.—Among the various subjects on trial in the gardens of the Royal Horticultural Society at Chiswick may be mentioned some excellent white Pelargoniums. These are worth seeing and comparing side by

side by those interested in this class of winter flowers. It is true we may see the self-same kinds at various exhibitions, but in these latter, culture and the undoubted influence of locality carry great weight. On the other hand, side by side in the gardens referred to all receive identical treatment. Several kinds are very fine and exceedingly pure and good in form.

Aster grandiflorus.—A fine bush of this excellent Starwort, the largest and perhaps the finest of all the race, though, unfortunately, too late to be of service in the open ground, was exhibited by the Messrs. Veitch at the Drill Hall the other day. Though too late for the open border, it makes a capital pot plant for the conservatory or greenhouse, and, indeed, in point of beauty and utility surpasses numbers of the more tender subjects that are grown under glass. The large solitary flower heads are produced on stems surrounded by small blunt leaves that closely resemble some species of *Diosma*.

Hybrid Nerines.—The beautiful lot of hybrid Nerines brought to the Drill Hall from Andoversford by Mr. H. J. Elwes on Tuesday last attracted a good deal of attention. The collection was almost entirely composed of seedlings, and contained many beautiful things in the five or six dozen plants brought to the meeting. In such a number it was scarcely possible to note any of inferior merit, though of necessity not a few exhibited similarity, both of form and colour. As plants requiring but a minimum of care and attention and flowering so long during the dull months of the year, these beautiful Nerines are welcome.

Gazania pygmaea lutea.—The more than usual amount of sunshine of late, coupled with the assisting rains, has apparently given a fresh impetus to not a few comparatively hardy flowering plants. Among this number the above may be cited as flowering abundantly in the closing days of October. Near by also the pure white kind was equally good, while the effect in this instance was considerably enhanced by a display of blossoms from large tufts of the hardy *Plumbago*, *P. Larpetæ*. The bronzed foliage of the *Plumbago* and the blue flowers were in striking contrast to the large spreading flowers of the *Gazania*.

Lathyrus violaceus.—The vagaries of plants in growing in some gardens, while they refuse to succeed in others more likely to suit them, are illustrated by a note I have from Mr. A. K. Bulley regarding *L. violaceus*, one of the Californian Peas mentioned on page 352 of THE GARDEN. While this Pea has been a failure with me and with others, it grew like a weed in Mr. Bulley's former garden at West Kirby, Cheshire. One's regret at being unable to grow it is greatly modified, if not altogether removed, by being told that the flower is poor and that the plant was left behind when Mr. A. K. Bulley removed to Neston.—*S. ARNOTT.*

Oenothera tetraptera rosea.—This is one of the most beautiful of the sub-shrubby members of the Evening Primrose family. The plant attains about 18 inches high and is of neat appearance. During summer and for a long time during early autumn the plant blooms very freely, the flowers being among the most beautiful the genus contains. The blossoms at a distance appear of a beautiful pink shade, but closer examination reveals a groundwork of white, with an exquisite rose-pink shade at the edges of the petals. The veins are also of this latter shade and impart a very beautiful appearance to this pretty and useful subject.

Abutilon vexillarium.—This well-known climber has been among the most profuse flowering of wall plants this season at Kew. The example in question is trained to a low wall in front of the Sarracenia house, and though naturally restricted in height, has flowered most abundantly for several months past, and only recently was carrying a fine crop of bloom. The position occupied by the plant is not particularly favoured, while abundant evidence remains that, given plenty of space for its branches, this pretty plant

would prove a most interesting subject in the garden. The drooping flowers of crimson and gold are very ornamental.

Crocus sativus Pallasii of Patras.—Those of us who are unable to flower year after year what is known as the typical *Crocus sativus* will not regret making the acquaintance of some of the forms more amenable to our climate or soil. Here I am unable to flower *C. sativus* after the first year, but some of the varieties bloom regularly. The variety *Pallasii* is one of these, and last year and this a form from Patras has pleased me much. Rather small, pure white on the exterior with the exception of some deep yellow at the base, it looks pretty with its pointed segments. The interior is also white, set off by the scarlet stigmata. These are brighter than in Mr. Maw's drawing of the white variety of *C. s. Pallasii* in his monograph.—*S. ARNOTT.*

Lithospermum prostratum.—Quite recently this pretty rock plant has sprung into blossom anew, and now the tufts, that have been more or less shabby during the great summer heat, are attractive with numbers of the deep Gentian blue flowers. Occasionally this desirable plant goes rusty and bad in the centre, and when past a certain age is not the most easy of hardy plants to transplant. For this reason it is better to rely upon young plants, numbers of which may be rooted from cuttings inserted now in very sandy soil. One of the essentials for success with autumn cuttings is that they be stripped off with a heel attached and inserted with no preparation beyond the removal of a leaf or two at the base. Frequently when cuttings of this plant are made to a joint they perish, while if inserted as suggested a large number root readily. Small freshly-formed shoots not more than 2 inches long are best.

Lathyrus pubescens.—In the notes on Everlasting Peas accompanying the coloured plate of *Lathyrus pubescens* in THE GARDEN of October 29 I mentioned that I was under the impression that I had received the seeds from Mr. W. Thompson, of Ipswich, but that I could not find these offered in any of his catalogues. I now find that the seeds came to me through the kindness of Mr. W. E. Gumbleton, who had received them from M. Ed. André, who introduced *L. pubescens* into Europe. Mr. Gumbleton now favours me with the information that a reduced-sized plate of this Pea as grown in M. André's garden at Lacroix appeared in the *Revue Horticole*, and that the plant figured in the *Botanical Magazine* as *L. pubescens* is *L. tomentosus*. I am grateful to Mr. Gumbleton for this information, which gives me the opportunity of giving due credit to him and to M. Ed. André. It appears that of these who received the seeds from Mr. Gumbleton, I was the only one who was so fortunate as to flower this charming Pea.—*S. ARNOTT, Carsethorn, by Dumfries, N.B.*

Chrysanthemum Henry Weeks.—In your issue of last week you state that a certificate was awarded to Mr. Wells for *Chrysanthemum Henry Weeks*, whereas it was awarded to myself.—*H. WEEKS.*

The Eucharis mite.—"C." in his note on the *Eucharis mite* at Kelham Hall in THE GARDEN (p. 352), is not quite right as regards the way in which the plants were treated. About an inch of fresh soot was put on the surface of the soil, and then the plants were watered with paraffin and water, a wineglassful of paraffin to two gallons of water. Afterwards the plants were always watered with soot water. No other manure of any kind was given them. After this treatment they were of a better colour than they had ever been.—*F. STEADMAN.*

Names of plants.—*Millands*.—*Acanthus spinosus*.—*R. Sydenham*.—*Antirrhinum Asarina*.

Names of fruit.—*J. Pitts*.—19, *Burré* Diel; 22, *Old Colmar*; 24, not recognised; 26, *East Beurré*; 27, *Clapp's Favourite*; 28, *Pitmaston Duchess*; 29, *Beurré Hardy*; 30, *Beurré Clairgeau*.—*J. Stigg*.—Apples: 1, *Cornish Gilliflower*; 2, *Yellow Ingestre*; 3, *Scarlet Nonpareil*. Pear: *Comté de Lamé*.

FERNS.

RESTING FERNS.

THE time is now at hand when many Ferns which make periodical growths will, when required to make a good display in early spring, be much benefited if kept quite dormant, withholding water and keeping cool. Drying off should never be done while the plants are making free growth, but after they have well matured one set of fronds and before another whorl has made a start. Some of our best early spring Ferns are obtained by treating them in this way. Take the *Pteris serrulata* section. Those that are kept in a low temperature from now to January and then placed in heat and given a good start, will make much finer plants than those kept in heat and forced into unnatural growth. I have frequently experienced the disadvantage of giving too much heat to Ferns from October to January. Those that make growth during this period do not as a rule make perfect and well-developed fronds, the consequence being that the crown is left very weak, and then it is late in the spring before the plants make a fresh start. Even then they do not start with the vigour of those that have had a natural period of rest. The above remarks are intended to apply to Ferns which are naturally evergreen, but there are several of our most beautiful Ferns which are deciduous, and to keep these in active growth late in the season is disastrous. I believe it frequently occurs that such beautiful Ferns as *Adiantum speciosum*, *A. palmatum*, *Nephrolepis Bausei*, and others are lost through not paying proper attention to their natural period of rest. Sometimes inexperienced growers make the mistake and throw them away for dead after they have lost their fronds.

Leucostegia immersa, one of our prettiest Ferns for summer work, loses all its fronds in the autumn and remains dormant for a considerable time. The earlier the plants are ripened off, the earlier will they start in the

spring. They should be kept cool and moderately dry until they show signs of starting, when they should have more warmth and moisture and be well exposed to the light. It is a mistake to keep Ferns which are naturally deciduous too dry. A moderate temperature and sufficient moisture to keep the underground rhizomes from shrivelling will ensure the best results. It is not safe to rely on the natural seasons to rest Ferns, for when grown under artificial conditions they may be making free growth at the time they ought to go to rest; and then they must be allowed to perfect their fronds, which will mean that the crown will be perfectly developed for making a new start after the proper period of rest, while if ripened off prematurely, the crown will be very weak. Although the plants may make a new start, the fronds will be small, and probably after making a vain attempt to grow will dwindle and die. I believe there are more choice Ferns lost through giving too much heat and moisture during the autumn than from any other cause.

A. H.

Adiantum Farleyense.—Grown in a 6-inch or 7-inch pot this is very useful for vases. Opinions differ as to the best soil to grow it in. I get the best results by using turfy loam, with a good portion of rough sand and a little broken charcoal. It requires good drainage. My plants stand on a stone which covers the water tank in the stove. I am convinced it needs a lot of heat. I have some plants planted out at the warmest end of a stove, where the boiler is, and they are thriving grandly, making large deeply coloured fronds.—DORSET.

Davallia Mooreana.—Among the free-growing members of this race none possess a wider value for general usefulness than this well-marked species. Too frequently, however, the plant is confined entirely to pots, yet it should be apparent by the free running character of the rhizomes that, afforded the opportunity, it is a plant which would quickly cover a large space. To do this, however, a certain surface area is needed that can only properly be afforded when the plant is

grown in a basket. In this way in a warm, moist house the plant grows freely, producing handsome fronds upwards of 3 feet long and proportionately broad. The spreading habit of the species specially fits it for this method of culture.

PROPAGATING BRITISH FERNS.

OF the various methods of propagating, that from spores is the best where this is possible, but there are some fine varieties which never produce spores, and others which, to ensure having them true, must be propagated by other means than spores. However, where spores can be obtained it is always advisable to sow, for seedlings not only make the best plants, but some improved varieties may be obtained. In selecting fronds for spores, those that have only just begun to open the spore cases should be taken, and in the case of the crested or other choice varieties, those with the most distinctly developed characteristics should be selected. Several of our prettiest garden varieties have originated from a frond or portion of a frond that has shown some slight difference from the normal forms. After collecting the spores they should be properly dried before sowing. Although Fern spores will retain vitality for a considerable time, I find the best results are obtained from those that have not been kept long, though I believe it is a mistake to sow directly they are collected.

Good loam is the best material for sowing spores on. This should be prepared by spreading it out and watering it so that all weed seeds may germinate and be eradicated. Care should also be taken that there are no worms in the soil. The pots may be filled firmly to within about half an inch of the tops, a little powdered charcoal and crock-dust sprinkled over the surface, and a good soaking of water given, after which the spores may be sown thinly. If covered with glass and stood in a shady position where it is not too dark they will soon germinate. Spores that are sown during the summer or autumn should be kept in warmth through the winter. In fact, they may be treated much in the same way as the more tender Ferns.

Of *Aspidium* (*Polystichum*) *angulare* there are several varieties which are prolific, that is they produce young plants on the fronds.

A number of bulbils are formed at the base of the pinnae close to the main stalk. If the fronds are pegged down on suitable material roots will be formed and young plants soon established. Although it is possible to propagate from fronds that have been taken off the parent, it is much safer to peg them down and get them rooted before taking them off. Some of the *Scelopendriums* produce tiny bulbils round the margins of the crested portions of the pinnae. *S. Kelwayi* is an example. These tiny bulbils may be cut off with a sharp knife or scissors. Only a very tiny portion of the frond should be attached. These pricked off and treated similarly to young seedlings and kept in a moderately warm position will soon show signs of growth. The best material to use for the surface of the pots is sand, Sphagnum, and peat chopped up and rubbed through a fine sieve. Some of the *Scelopendriums* may also be propagated by taking well matured fronds off close to the crown and cutting the lower portion of the stalk (or stipes) into short pieces. Treated as recommended for the bulbils they will form buds and eventually start away, but they are some time before the first fronds are produced, and care must be taken not to get them too wet, or they will decay instead of forming bulbils. The ordinary *Adiantum Capillus-Veneris* may be raised from spores, and all of the varieties are easily increased by division. The beautiful variety *imbricatum* is a curious instance of forming bulbils. I have never seen good spores of this, but in place thereof tiny bulbils are formed round the margins of the pinnae. It is the only instance among all the *Adiantums* that I have seen, though solitary bulbils or plants are in several instances formed at the extreme points of the fronds, as in *A. caudatum*, *A. dolabrifolium*, &c.

There is no particular season for propagating hardy Ferns, but spores collected late in the summer usually prove the most fertile, and if sown during the autumn, with care they will go through the winter and will have all the following season before them to get well established and form good crowns before such as are deciduous lose their fronds. A.

ROSE GARDEN.

CLIMBING YELLOW ROSES ON STANDARD BRIERS.

YELLOW climbing Roses are so popular that the so-called white *Maréchal Niel*, which, however, is not white, has been rather coldly received. "P.'s" selection (p. 351), short as it is, calls up mostly old popular favourites. Given a sheltered place "P." says, truly enough, that *Maréchal Niel* will grow into a glorious weeping tree. For many years I grew such trees in quantity.

In addition to sheltered sites, moderate feeding is essential to the longevity and free flowering of climbing Roses. Perhaps it is not too much to say that more Roses are killed by over-feeding than by the effects of frost. A gross diet produces a gross habit of growth in our Roses, and when to these two are added late growth and blossoming Roses become tender. To prevent this occurring, "P." recommends occasionally lifting and replanting these Roses, say once in five years, as a check to excessive growth and a means of increasing the number of the blossoms. A moderate regimen for the roots will provide an equally effective and safer check to growth and aid to flower production. Another curious and interesting change is effected through the growth of Teas and *Noisette* Roses as standards on the Dog Rose. It is desirable before proceeding further to note the question of the best height for this form of Rose tree or bush. Three considera-

tions should mainly determine this. The first is the artistic effect of Roses of different heights. Rosarians are prone to combine two classes of Roses under the general head of climbing or weeping Roses, while in reality the two are widely different in artistic or landscape effect. *Maréchal Niel* is a good example of a weeping, while *Gloire de Dijon* may be accepted as a good example of a climbing Tea Rose. "P." prefers a stem a yard high. I prefer Dog Rose stems from 3 feet to 5 feet or more high for *Maréchal Niel*.

The second point is the effect of the height of the Rose stem on the hardness of the Rose budded on it. Some years since I made numerous observations on the hardness or tenderness of Tea and other Roses, that went to show that within certain narrow limits the closer to the ground the more tender. Hence most Rose growers are familiar with the fact that the frost cuts their Teas down to the ground, or an inch or two under it, while the self-same Roses mounted on Briers from 2 feet to 5 feet or 7 feet high escape unharmed. One more curious thing happens to such golden Roses as *Maréchal Niel* when we mount them on Dog Briers of considerable height. As a rule, the *Maréchal Niel* only flowers once in the open air, even in the more favourable sites. Work it on the Dog Rose 3 feet or more high and it soon begins to bloom, twice or oftener. One more point, and it is perhaps the most interesting and mysterious of all. The older the plants are the more profusely they bloom, until this best of all our yellow Roses practically becomes a perpetual bloomer. D. T. F.

Pruning and propagating Tea Roses.—"D.'s" complaint of the over-pruning of Tea Roses (p. 351) is very often heard. The chief fault to find with many choice Tea and other Roses is that they make so little progress. They are pruned so hard or grow so little that they fail to make any headway. No doubt, as the editor says, the *Manetti* stock has much of this to answer for, as well as the severe pruning. Teas and Hybrid Teas, as well as most other Roses, are best worked on the seedling Brier or Brier cutting. Even on this strong root stock they are often cut to pieces. It needs many years to teach rosarians that the pruning-knife is mostly a necessary evil among Roses, and not the emblem of either common sense or uncommon skill. When we come to plant our Roses primarily to furnish our lawns, shrubberies, beds, and flower borders, we shall then learn the art of training them better, and pruning them less or not at all. Tea Roses, especially those on their own roots, may generally have pretty fine heads. Cuttings of Tea Roses are as readily rooted as those of Currants and Gooseberries. Insert the cuttings, with a heel if possible, about 4 inches deep on a north border, tread them in firmly in rows from a foot to 18 inches apart, and some 80 per cent. of the cuttings will root without further trouble. Tea Roses on their own roots renew their youth if desired every year. It is hardly possible to lose the plants through stress of weather, for if cut down to the ground by the frost one year they recover themselves the next without either loss of stature or of vital force.—D. T. F.

NOTES AND QUESTIONS.—ROSES.

Tea Roses and Mignonette.—Mr. Crook's note on the Tea Roses and Mignonette in the flower garden at Honeycott House (p. 350) reminds me of a fine display I saw at Ossington Hall. A well-sheltered garden was set apart for Tea Roses, and in each of the beds Mignonette had been sown, the two subjects forming a most pleasing picture, to say nothing of the delicious fragrance given off by the Mignonette.—C.

DARTMOOR IN SEPTEMBER.

AFTER the long spell of drought, when, in spite of an occasional shower, the grass remains sere as in August and the great *Hydrangea* bushes droop their wilted leaves along shrubbery and drive, it is a pleasure to seek for a while the adjacent uplands of Dartmoor, the sanatorium of South Devon, and there, at a height of over 1000 feet above sea-level, breathe the fresh heathland air and gaze at the sheets of purple and gold that lie spread beneath the eye—aeres upon acres clothed with the purple mantle of the Heather and the bright gold of the Gorse—a pageant of colour that acquires softer and less definite hues as it recedes from the view, and at length, afar, melts into the infinite blue of the atmosphere, nowhere so exquisite as on the spacious moors, that limns distant tor and heath in tender monochrome. No signs of aridity are visible at this high level, for the little pastures or "new-takes," here and there filched from the moor, are emerald-green, and that white sheet that rests like a snowdrift in yonder slight depression is formed of the flossy seed-vessels of the Cotton Grass, growing in a spot where, even after the comparative drought of the season, it is not wise to venture if a dry foot be a desideratum. The streams run crystal-clear around the huge boulders and beneath the rude megalithic bridges built in far-off recordless days by unknown hands, whose only other mementoes are the hut-circles, menhirs, and kistvaens that still exist, scattered over the length and breadth of the moorland, concerning which, so remote is their antiquity, even legendary lore is silent. Here in the shadow the little troutlets lie, ready, at a movement of hand or foot, to speed, like brown streaks, down the sunny stream, while on the flat stone, hard by a bank where diminutive Hairbells hang their tiny cups, the dipper, in modest brown and white attire, pauses a moment to sing its brief song ere taking the water or flying, with rapid wing, to some more distant haunt. When the last glint of the setting sun has faded from the stream and the heavy due is falling, a filmy veil of diaphanous haze slowly rises over its surface. Later on, in the clear moonlight, the vapour assumes a denser appearance and hangs, fleecy-white, along its course. Motionless the white cloud lies through the windless night, until at length, stirred by some zephyr of the dawn, it slowly drifts away to wreathe the dew-spangled slopes of the tors with trails of transparent mist, or dissolves beneath the morning sunrays that gild the gossamer.

It has been written by an enthusiastic admirer of Dartmoor that a wet day there is preferable to a dry day anywhere else, and though few, even of its lovers, would be inclined to echo that sentiment, it is undoubtedly true that the due appreciation of its charms becomes possible only by a wide knowledge of the moor in varying conditions of weather and from its highest to its lowest levels.

Perhaps the sudden change in the character of its scenic effects is one of the chief charms of this Devonshire moor, for scarce a mile from its open sweep the deep rifts in its confines hold sanctuaries of soft verdure and rippling waters such as one would look for rather among the gently dimpled valleys of the lowlands than in close proximity to the austere grandeur of the tors.

Here one has the rugged fastnesses of Great Staple Tor towering heavenward, while at its foot the little river Walkham plunges down from the open moorland through Merivale Bridge, and, skirting Vixen Tor, noblest in outline of all the Dartmoor granite masses, meanders, gurgling round the boulders and foaming over cleft rocks, through a deep valley, here overhung by trees, there edged with grassy spaces where the great *Osmundas* arch their lofty fronds, and in the early summer the *Orchises* paint the sward with soft colour. Now, in September, the berries of the Mountain Ash are clusters of bright scarlet on its banks and the *Whortleberries* are purple-ripe. Lower down the breadth of the waters widens, and in an open glade, where in the springtide of the

year the Wood Hyacinths spread their shimmering veil of blue, the Bracken growing on the margin already shows here and there a glint of gold, while the horrid Bryony trails that hang from the Hawthorn bushes are slowly changing their tints from green to crimson. The Oaks interlace their branches above the boulder-strewn stream, very clear and shallow now, but of a strangely different aspect when in the dark winter days the low skies open their flood-gates, and amid the thunder of the rolling boulders, the Walkham rushes down in spate, a turbulent brown flood, swirling breast-high round the tree boles and submerging the straining undergrowth beneath the hurrying foam-rifts that fleck its surface.

Many and varied are the prospects afforded by the high-lying downs, but the impressions are ever fraught with beauty, albeit often of a sombre nature. There is the eerie desolation of Cranmere Pool bereft of all vegetation save tussocks of coarse herbage and Rushes; the crease in the moor that shelters the weird, stunted Oaks of Wistman's Wood, gnarled and contorted dwarfs, whose age is measured by centuries, through which of nights the fabled Yeth hounds hunt their phantom quarry; the majesty of the tors, that loom gigantic from the cloud-wreaths "where the wet hill winds weep," or on such a day the glimpse revealed through the eddying mists of Plymouth Sound lying in the sunlight like a silver mirror full fifteen miles away.

S. W. F.

ORCHIDS.

GROWING ORCHIDS IN LEAF-MOULD.

IN the "Dictionnaire Iconographique des Orchidées" of M. A. Cogniaux there is, writes M. Ed. André in *Le Revue Horticole*, a very interesting note relative to the cultivation of epiphytal Orchids in leaf-mould, as practised by M. de Langhe-Verveene, of Brussels. According to M. Cogniaux, the plants cultivated in this way flower more freely than they do under other ways of cultivation. In order properly to test the virtues of leaf-mould in this connection, it is necessary the plants should be recently imported. They should be placed in a pot of prepared leaf-mould. A stout slab is placed at the bottom of the pot, and the plant is put on a low mound of earth and the surface covered with a thin layer of living Sphagnum. The degree of moisture required to keep the Sphagnum always fresh should be kept up by watering. No other kinds of vegetation—mosses, fungi (microscopic or other) penetrate the soil, and the roots of the Orchids are enabled to draw their nourishment from the mould without the air getting into the pot. The mould, which is well rotted, is composed of 30 per cent. of Oak leaves, 15 per cent. Hornbeam, 15 per cent. Alder, 15 per cent. Ash, 15 per cent. Beech, 10 per cent. coarse sand. The proportions of each of these elements applicable to one or other of the species of epiphytal Orchids now cultivated in greenhouses cannot, however, be precisely laid down; experience will show. The essential thing is to locate the plant in the position which is most suitable to its natural mode of vegetation, and in watering to carefully avoid any excess of moisture; it is enough to give the superficial watering necessary to maintain life in the Sphagnum. If the leaf-mould is well drained success is assured.

* I should not like to attempt the growing of sub-epiphytal Orchids in what we call leaf-mould in British gardens, but the leaf-mould (terre de Bruyère) of the French and Belgian gardens is a very different thing, and a substance in which most plants, especially the peat

lovers, or shall I say lime haters, such as all the Ericaceae, grow well. The luxuriant manner in which most plants thrive in the continental product is little short of wonderful to those who see it employed for the first time. I have known amateurs so enthusiastic that they imported leaf-mould from Belgium for Heaths and Azaleas, and with good results, though, broadly speaking, our Hampshire peat and Reigate sand seem better suited for these plants as grown under the English system of culture. It must be distinctly understood that Belgian leaf-mould is very different in many ways from our English product, and probably more care and attention are devoted by specialists to its preparation.

Given good and ample drainage and a mixture of clean Sphagnum Moss, or even a top dressing only, as M. André suggests, I can well understand that newly-imported Orchids, especially Masdevallias and Odontoglossums, would do well in the Belgian material. When at Moortelbeck last spring I saw superb Odontoglossums and Cypripediums growing so robustly that one instinctively asked, What is the secret; what are the potent fertilisers used to obtain such grand results? M. Lucien Linden turned out a plant or two, and apart from a little extra drainage the material in which they were growing looked like an ideal compost for Fuchsias rather than for Orchids. But I am one of those who believe that if light, air, moisture and heat are right, and there is plenty of diffused light and plenty of fresh, pure, and clean rain-water, the actual compost employed for Orchids is of secondary importance. In a word, the compost is more a vehicle for regulating the supply of moisture and air to the roots than anything else, and for this purpose "terre de Bruyère" is in Belgium as good, or perhaps better, than anything else if surfaced with living Sphagnum in the usual way. At the same time, I should be the last man to advise the growth of any Orchids in English leaf-mould in English Orchid houses, and in the English climate, because all the factors are so essentially different in all ways. After all, "recently-imported" Orchids will up to a certain point grow well in very diverse kinds of composts, other factors being right, but what most Orchid growers desire is a compost that will keep old-established plants healthy and free-flowering for as long a period as possible. For this latter purpose nothing has so far surpassed fibrous peat, crocks, and Sphagnum, with the addition or substitution of the best loam fibre for some of the stronger-growing sub-terrestrial kinds, such as Cypripedes, Cymbidiums, Phaius, &c. When we are told that "the roots of the Orchids are enabled to draw their nourishment from the mould without the air getting into the pot," one feels that one of our oldest and most cherished of traditions as to Orchid culture is endangered. Most of our best Orchid growers act so as to encourage the free aeration of the compost in which most Orchids are grown—the raft, the block, the perforated pot, and the teak wood basket all favour this idea, and experience shows pretty plainly that the idea is correct, as measured by the generally good results obtained.

At the same time, having seen the almost equally good results obtained with Orchids and other rare plants as grown in the peculiar leaf-mould of France and Belgium, I would bespeak a fair and impartial hearing of M. André's point of view. We in England succeed in one way and our French and Belgian friends attain their results by different means; and both have to do their best with the climate and materials with which they have to deal. As M. André himself says, no precise rules can be laid down, but

"experience will show" what is best to do under different conditions.

F. W. BERRIDGE.

Dendrobium superbiens.—Like several others of the Australian section this Dendrobium is not always a success under cultivation, but when well done it is certainly a beautiful Orchid. It varies considerably, some of the better forms ranking among the finest of Dendrobiums and being distinct in colour. Plenty of warmth while growing and a thorough ripening of the pseudo-bulbs are necessary, and, if this can be arranged, the plants always start more freely and flower more profusely when they take a good rest in early summer.

Cypripedium Allenianum superbum.—This is a remarkably fine hybrid, and a twin-flowered spike I recently noted shows what a beauty it will be when it becomes better known and more plentiful. The raisers of such hybrids render a good service to horticulture. The kind referred to is a cross between *C. Spicerianum* and *C. Curtisi*. It has a splendid dorsal sepal not unlike that of the former, the petals and pouch of various tints of green and brown. No doubt it will be freely propagated, and it should eventually become a very popular kind.—H.

Miltonia Peetersiana.—I noted this uncommon hybrid in flower recently in Mr. R. I. Measures' collection at Camberwell. Its reputed parents are *M. spectabilis* Moreliana and *M. Regnelli*, and not only are the flowers intermediate in form, but the growth of the plant also shows signs of each parent. From *M. Regnelli* it gets the bright purple disc to the lip, while the colour of the sepals and petals is a vinous purple more like that of the Moreliana types of *M. spectabilis*. The plant was exhibited last year at the Drill Hall, when it was given an award of merit by the Orchid committee. It is a welcome addition to the list of Miltonias, as the flowers are neat and pretty, the plant apparently free-flowering and of healthy growth. Probably it will thrive well if treated as advised for *M. spectabilis*, that is given a thin, well-drained compost, an intermediate temperature, with shade from the brightest sunlight only.—H.

Cattleya Maroni.—This is one of the most distinct and charming hybrid Cattleyas that have ever been raised. It is the result of crossing *C. velutina* and *C. Dowiana aurea*, traces of both parents being apparent in every portion of the flower. The sepals, each upwards of 3 inches in length and over an inch in breadth, are yellow, suffused with a bronzy shade of brown; the petals similar in length, of fine form and substance, bright yellow, suffused with a bronzy shade and veined with a purplish hue. The front lobe of the spoon-shaped lip is yellow, heavily suffused in the centre with rose-purple, and prominently veined crimson. The front of the throat is rich yellow, mottled with purple; the small side lobes rose with numerous yellow lines. It was raised by M. Ch. Maron, Horticulteur, 3, Rue de Montgeron, Brunoy, France, while he was gardener to M. Fournier at Versailles, where he was most successful in the raising of seedling Orchids, especially Cattleyas. Such fine varieties as *Cattleya Andreana*, *C. Fernand Denis*, *Lelio-C. Lady Wigan*, and other varieties, which have been frequently referred to in THE GARDEN, were raised by him.—C.

Epidendrum radicans.—This useful and bright-flowering Epidendrum has but one fault, and that is its rather rambling habit. This renders the use of some support necessary, but, this provided, it is a very free and beautiful plant that all cultivators should grow. It has been freely used by hybridisers, and its progeny is in every case I know bright and beautiful plants. The first and perhaps the best known of these is *E. O'Brienianum*, this having *E. veetum* for its other parent, while hardly less known is the bright little *Epiphronitis Vitchi*, obtained by crossing this species with *Sophronitis grandiflora*. Several others have been raised since

these, and doubtless as time goes on we shall see many of our best Cattleyas and Lalias crossed with it, these having already been used as seed-bearing parents with effective results. It comes from South Mexico, and is one of the introductions of Mr. G. Ure-Skinner. Under cultivation it delights in a fresh, moist atmosphere with abundance of air moving about it and not too high a temperature. Where the little stem-roots have the chance of rooting into whatever is used for the support of the plant, stronger growth results. But this is not absolutely necessary, especially if the base is planted in a good compost and kept in order. The blossoms are very bright red with an orange centre, and are produced in small terminal corymbs.—H.

Angræcum bilobum Kirki.—If the flowers I have noted as this variety for several years are true, it is difficult to say why it was ever given varietal rank, for I have noticed but little difference in the two, and if anything the typical plant is the better. The flowers are small, pure white in front, the spur of the lip tipped with orange, and they are produced freely upon spikes containing about half a dozen. It is a pretty plant when well grown, and for its culture requires a warm moist house, with ample light. Grown in small baskets or pans suspended from the roof it has a pretty effect when in flower. The species is a native of the west, and the variety the east coast of Africa.—H. R.

NOTES OF THE WEEK.

Polygonum capitatum.—This very pretty species is a most continuous bloomer and one of the most suitable for the rock garden, where it blossoms as profusely as ever. The plant has never ceased flowering for many weeks and the singular little heads are very attractive in a mass.

Rosa indica sanguinea.—Masses of this richly coloured Rose are still gay with almost endless buds and many expanded blossoms, the former especially rich and well coloured, and, owing to the lessened sunlight and heat, they remain long in the bud stage. It should be more freely employed because of its abundant and long-continued flowering.

Begonia President Carnot.—This free-growing variety is valuable for late autumn flowering, and, though not one of the most brilliant in point of colour, is sufficiently attractive and free-blooming to merit general approval. In the manner of growth and flowering it bears comparison with *B. coccinea*. The blooms, however, are less brilliant than in that species.

Nymphaea Lotus rubra.—Among the tropical or sub-tropical aquatics this is a most desirable kind, and one that pleases when in flower by reason of its colour and also the size of the blossoms. The variety, too, is rather free flowering, and where blooms of this character are especially valued, this one at least should always be grown where a stove temperature can be maintained.

Funkia subcordata.—I am surprised to learn that J. H. W. Thomas, Belmont, Co. Carlow, has failed to flower *Funkia subcordata grandiflora* out of doors. It seems quite established in a sunny part of the rock garden here, and has bloomed well both this season and last. The winter of 1897-98 was certainly very mild, but I find a covering of ashes quite sufficient protection for it.—M. KINGSLEY, *Bourne Orchard, Hertford.*

Momordica cochinchinensis.—This brilliant fruiting climber may now be seen in the stove aquatic house at Kew bearing several large highly coloured fruits. In shape the fruits are roundish ovate, of the size of a large Melon, and thickly studded over the entire surface with rather blunt-pointed prickles or spines each nearly, or quite, half an inch in length. The fruits are conspicuous by the rich red-vermilion colour of the exterior, the spines being also of the same vivid colour.

Hedychium flavescens.—The beautiful primrose tint in the flowers of this species affords a most pleasing and welcome variety among these moisture-loving plants of the tropics; and not only welcome in point of colour, for the fragrance is also unique, that from a spike or two naturally,

however, containing a larger number of individual flowers, being sufficient to pervade quite a large space. Vigorous and quick-growing by nature, these plants are best suited when the proper conditions of heat and moisture are given. Given these, the details of culture are simple.

Erica vagans alba.—The white Cornish Heath has been in bloom here for an unusually long time, and to-day (November 14) is still giving a good display of flowers on the summit of the rock garden. Left undisturbed for several years a plant soon grows to large dimensions, and even when out of flower its evergreen foliage is pretty. The hardy Heaths have often been commended in THE GARDEN, and the coloured plate which recently appeared cannot fail to bring them under the notice of growers of hardy plants who have overlooked their beauties.—S. ARNOTT.

Androsace lanuginosa.—Although November has now half run its course, the silky-leaved Rock Jasmine is still in flower, giving a welcome feature with its silvery silken foliage and its pretty flowers. It has been frequently mentioned in these columns, but one can hardly over-praise it because of its prolonged period of bloom. Such flowers are very precious in our rock gardens because of the pleasure they give for so long a time. I do not find the variety *Leichtlini* possess this quality to the same degree. Pretty though it is, it lasts a much shorter time in flower.—S. ARNOTT.

Benthamia fragifera in fruit.—I am sending a few fruits of *Benthamia fragifera* from a tree growing here on a south wall. The tree is 15 feet high and about as much through. There were two trees here until the hard winter of 1894-95, when one was killed and the present one much injured. It has not fruited since until this year. I do not remember to have seen it fruit so well before or the fruit so fine. The birds have started eating the fruit and I fear will soon clear it.—JAMES WEBBER, *Dunster Castle Gardens, Somerset.*

* * * The largest and most beautifully coloured fruits of this shrub we have seen.—ED.

Crocus longiflorus.—Dull days and leaden skies do not suit the Crocus well. It is seen at its best on bright days—never too plentiful in November. Yet patches of some of the Crocuses even if unopened look, if not gay, at least cheerful among the Saxifrages and other dwarf plants in the rock garden. One of the brightest of these in this state is the old Crocus longiflorus, which is cheap enough to be planted freely where others can only be planted in ones or twos. It increases fairly rapidly, too, so that one can soon have nice patches from a few corms. The bright lilac flowers please everyone at any time, but the pleasure is increased should a sunny day come when the flowers expand and entice the few adventurous bees which have dared the weather to scramble among the Crocus cups. A sunny, sheltered position in light soil suits this Crocus well.—S. ARNOTT.

Border Chrysanthemums at Kew.—Near the Victoria Gate entrance to the Kew Gardens may now be seen the remnants of a very fine display of border Chrysanthemums. Some of these are not usually planted out, and are, therefore, deserving of notice. Of this portion the best is a very old kind—*Gloria Mundi*—a variety well known, and in its day justly esteemed for its very fine colour. It is barely 3 feet high and incurred, the colour rich golden-yellow. Mrs. A. Le Moutl is a single-flowered variety of a crimson-amaranth shade, 2 feet. Mary Anderson, another single, 2½ feet, white and lilac; and Miss Rose, single, about 20 inches, with a perfect mass of its rosy lilac blossoms, are very showy. Other kinds used are Harvest Home, 2½ feet; President, amaranth, 3 feet; Golden St. Thais, 2 feet, of good colour, but not so effective as *Gloria Mundi*. These with General Hawkes, G. Wermig, and Fred Maronet were all disposed in large wedge-shaped blocks around a circular bed. A few kinds were past, and among them the two last named. The remainder, however, were

good save Sylphide, a yellow which is too late, as it was only opening in the early days of November, too late for ensuring a good display in ordinary seasons.—E. J.

Luculia gratissima.—“C. N.,” writing of this plant in your issue of November 12, says, “when the bloom-trusses are expanding in spring.” Here there are four plants, which may almost be called small trees, of *L. gratissima* reaching quite to the roof of the conservatory, but they are beginning to flower now, and I have a note that last year they were in their fullest beauty on December 12, when all the trees were covered with the large Hydrangea-like trusses of bloom and lighting up the conservatory at the darkest time of the year. By the new year the flowering period is almost past, and they are then soon after cut back to mere poles to repeat the flowering process next winter. Does *L. gratissima* usually bloom in spring? Here I find it most valuable in affording abundance of sweet-smelling cut flowers at the dullest time of the year. The trusses will not travel, but if taken at once from the conservatory and placed loosely in bowls of water they last two or three days, and are very fragrant at first.—SHERBORNE.

Crinum Moorei.—This is one of the handsomest of the genus, or at least that section of it having any pretensions to hardiness. It is, however, only hardy in very favoured positions, or where special attention is given to a few such things that may be flowered in the open by such means. Such opportunity, however, is always offered where large glass structures exist, and here on the northern side, by reason of the uniformity of the conditions existing, such plants are usually a success. On the southern side of such a building there is a danger of the subjects starting too early and being checked by spring frosts. This, however, does not necessarily apply to this plant, which under these conditions is capable of making a really fine display in the open, the stout, almost massive scapes reaching fully 3 feet high and bearing numbers of the handsome drooping flowers, the latter white, heavily tinted with rose-pink. The vigorous nature of the plant, however, requires a good as well as deep soil. Equally good is the plant when grown in the conservatory or cool greenhouse, where it should either be grown in tubs or planted out. If grown in pots, these should be strongly banded with hoops of iron to prevent the bursting so common with such free rooting subjects.

Dianthus superbus var. sinensis.—The variety here named is calculated to enhance the value of one of the most free-flowering species of Pinks, viz., *D. superbus*, a kind long known to the cultivator of hardy flowers. The flowers of the newcomer have quite a new and distinct shade of colour, which may be described as a purplish mauve hue. The variety is wonderfully free flowering, singularly delicate and pleasing in its delightful fragrance, and not less beautiful in the heavily fringed character of the flowers. Plants of this beautiful fringed Pink have flowered this season at Kew, where in sandy soil it has reached more than 2 feet high, and owing to the much-branched character of the inflorescence, is remarkable for the great profusion of its flowers. In these respects it resembles some other species of the same genus, which flower so abundantly in lowland gardens as to rarely survive the flowering unless special means be taken to obviate this. Doubtless, however, under certain conditions of culture plenty of seed will be forthcoming; this, however, is by no means the case at Kew, for this year at least. The conditions best calculated to ensure a crop of seed will be by treating the plant as a biennial, raising the plants in June or July, and, when planted out, not permitting them to flower at all in the first year. By thus deferring their flowering period a stronger tuft would be secured and probably an early flowering the year following, and in turn the chances of a good crop of seed ripening earlier. These fringed Pinks are usually most secure when the plants are grown in a comparatively poor soil.

STRATHFIELDSAYE.

STRATHFIELDSAYE, the Hampshire residence of the Duke of Wellington, lies on the high road about midway between Basingstoke and Reading, in Berks. It is about a mile from Heckfield Place, six from Winchfield, and three from Mortimer, on the Reading and Basingstoke line. It stands in a valley and beside a stream, for the river Loddon flows along in front of the mansion at a few hundred yards distance, and, broadening out just there, presents fine opportunities for water gardening, such as is now so popular. The illustration which shows the mansion front and the parterre flower garden exhibits in a marked degree that characteristic homeliness which differentiates it so much from architects' gardens. The parterre garden may be formal, as all such gardens more or less are, but every effort is made in the planting, whether in summer or winter, to deprive it of

Lilies, indeed flowers in rich luxuriance, whilst other beds or masses of shrubs or ordinary hardy or tender plants fill the intervening space. The two very fine Araucarias seen in the picture are but duplicates of others at the corresponding end of the garden.

Strathfieldsaye is very rich in noble trees, especially conifers. The grand specimen of Wellingtonia planted by a former duchess is without exception one of the tallest and noblest in the land. Possibly it has no equal. There is also a grand companion tree in a Picea Nordmanniana, which is of its kind perfect. But there are many others, for the rich alluvial soil of the Loddon valley seems to suit these trees remarkably well. Many noble trees are found that are far from common. Whilst the entire area of pleasure-grounds is very extensive, the whole is well kept and cared for. A very interesting feature is seen in the broad noble avenue of Yews that leads to the mansion, as

CHRYSANTHEMUMS.

CHRYSANTHEMUMS FOR HOME DECORATION.

DESPITE all that has been or can be said against the growth of large, well-developed flowers otherwise than for exhibition, there is no question about their beauty at this season of the year. But some of the famous exhibition kinds are absolutely useless for decoration. I do not grow for exhibition, but I like to have flowers as perfect as possible, and to this end cultivate those that look as well on the plants as they do on the show-boards, or rather look much better. As I anticipated some weeks ago, my flowers are well up to time and of better quality than usual, and this shows that the season has been not altogether a bad one, though, as my neighbour Mr. Tallack points out, insects of all kinds have been abundant

The terrace garden at Strathfieldsaye, Hunts. From a photograph by Mr. F. Mason-Good.

that defect and to avoid flatness. In the summer the majority of the beds are planted in the now much accepted mixed fashion, so that whilst no special colour or plant stands out markedly, there is a pleasing blending of colour and of form of growth that renders the beds exceedingly attractive. These are grouped on diverse levels to accommodate the natural fall of the land towards the river. The flower garden, though described as "terrace," is, as the illustration shows, void of balustrades, gravel walks, and other not always pleasing garden features. The flowers rise out of rich green turf. Somewhat remote from the house, and in the midst of belts of lofty trees and shrubs, is a more modest flower garden, of which one end is presented on page 407. Here, where lofty masses of shrubs shut out all else, the flowers constitute a primary feature. The two ends of this garden are of circus form, and each has beds filled in summer with Begonias, Fuchsias,

also is another in the fine avenue of Wellingtonias planted within the park beside the entrance road from Heckfield Common, where in all its solitary grandeur stands on a lofty column a statue erected to the memory of the founder of Strathfieldsaye, the famous Iron Duke.

The fruit and vegetable departments are both extensive and well cared for. The walled gardens with long ranges of glass offer to a gardener much the severest tests of his ability, and at Strathfieldsaye they well come out of the ordeal. About in the borders, however, flowers are largely grown, Carnations especially being grown in thousands, as also are hardy flowers of many descriptions. Great attention is given to early spring flowers, also to the flower beds, and the preparation of these occupies much space and labour. The Chrysanthemum is a prominent feature, and many hundreds are grown in pots.

and active, and the leaf-rust has been far too much in evidence. White varieties are always in demand and always admired, and there are many good ones. Mme. Carnot is an exhibition kind pure and simple, and though I have grown it since its introduction, I have never liked it, and shall discard it altogether this year. Mutual Friend is one of the most lovely Chrysanthemums ever sent out, and one cannot but wish it had a little better constitution. It will throw four or five splendid flowers from a plant in a 9-inch pot, but the foliage is apt to suffer unless very carefully grown, and for the purpose indicated one wants every leaf good down to the pots. According to my experience, this variety should be struck fairly early, say about the middle of December, and cut down in April. Take up three or four shoots, according to the strength of the plant, and allow one flower to each shoot. Emily Silsbury is a very fine white kind, rather too early in most

seasons, though not far out this year. It is a good grower and will finish at least a half-dozen fine flowers on a plant. Miss Elsie Teichmann is one of the finest whites, the flowers with broad curling florets, and the habit dwarf. As it retains its foliage to the base it is one of the very best for decoration. The old Elaine and Mlle. Lacroix are ehaste and beautiful kinds still worth a place. Among yellows none is more beautiful than Edith Tabor, the long beautiful florets being very elegant, but the tall, spindly habit spoils it. The well-known Phebus is good for decoration, so is Mons. Pankoneke, one of the finest of exhibition kinds. Lago Maggiore I have not grown, but intend to; I saw it recently at Livermere, and Mr. Tallaek thinks highly of it. Leaving out the Vivand Morel section, of which all are good, but especially Chas. Davis, I will at the risk of being tedious mention one or two others that are excellent for decoration. Mme. Marie Ricoud is good in every way. Eda Prass is unrivalled in its soft tinting, though perhaps a little stiff. Dorothy Seward is a pretty bronze that should be taken earlier than most to allow the large blooms time for their full development. G. C. Schwabe is one of the finest: always leaved well down if carefully grown, and the flowers sit on quite a cushion of foliage. John Seward and C. Shrimpton are of the best in their respective colours, and Miss Dorothy Shea is a refined and pretty flower. International, much as it has been decried, is a large handsome flower when at its best, and Thomas Wilkins is a fine free doer that should be grown by everybody. To those who want perfect flowers quite up to exhibition standard without enlarging their collection by taking up all the new varieties as they come out, I can recommend the above.

Respecting leaf rust, there is not, as far as I can see, any advantage in making the house smell like a gasworks by using sulphide of potassium about the plants. Any ordinary insecticide will prevent the spores flying about where it is brought into contact with them. A more likely means of preventing its spreading would seem to be syringing the bases of the plants and young shoots with a half ounce to the gallon solution, and clearing away to the fire all the old stems and foliage as soon as possible. Wherever sulphide is used, great care is necessary that it does not reach white lead paint in the house, or black, unsightly spots will result. SUFFOLK.

NEW WHITE CHRYSANTHEMUMS.

EVER since the days of Elaine, Fair Maid of Guernsey and Lady Selborne we have been adding to the list of fine white Chrysanthemums, and it seems doubtful if we shall ever surpass Mme. Carnot as a flower, although long experience only tends to prove that in Chrysanthemum matters it is never safe to prophesy, for it is always the unexpected that happens.

In late years there have certainly been some very grand additions to the many fine white Chrysanthemums in cultivation, some of which, however, seem to have passed away from the show boards, but are carefully preserved for other purposes by growers whose object is more to make an effective display, like those we see at the parks, than to grow solely for exhibition. Mlle. Therèse Rey, Baronne Ad. de Rothschild, Souvenir de Petite Ami and Mrs. J. Lewis, which was one of the finest and largest last season, are all fairly well known, and the same remark applies to such varied forms and shades of white as are to be found in Mme. Gustave Henry, Mlle. M. A. de Galbert, Antoinette, Mlle. Lucie Faure, Mme. Ferlat, all of M. Calvat's raising, and all more or less good. Simplicity, Mutual Friend,

Lady Byron, Miss Nellie Pockett, Mme. Madeline Expulson, and M. Louis Remy are constantly being met with this season, as also are Mrs. H. Weeks, Emily Silsbury, and one or two others equally well known. Although it met with little recognition at the floral committee of the National Chrysanthemum Society, I cannot help thinking that the very pure paper-white sport from Reine d'Angleterre called Miss Mary Leschelles is deserving of some attention, and will be acceptable to many growers, and that Jane Molyneux, shown at the same meeting, if not of the same purity of tint, is also destined to occupy a prominent position next season. Others, like Abbé Brosson, Dr. Noel Martin, Marie Calvat, Mrs. Bissett, Fée du Champsaur, Mme. Frederie Daupias, and Beauté Grenobloise are less well known than the preceding, but have been seen in fairly promising form. C. H. P.

CHRYSANTHEMUMS AT SWANLEY.

MESSRS. H. CANNELL AND SONS have usually a very large and interesting collection of Chrysanthemums, and this year's display is in no way below the average both for quantity and quality. The major portion of the Swanley novelties is housed in a large span-roofed greenhouse and is effectively arranged for the purpose of showing the blooms off to the best advantage. Here, as at most of the trade displays, novelties may be seen in abundance. The once well-known raiser, M. Simon Délaux, is represented by a set of curiously striped and spotted varieties, which, although somewhat novel, are by no means likely to excite much admiration by the ordinary English grower for cut blooms who still requires the heaviest and largest blooms that it is possible to get for his purpose, and it is largely upon the requirements of such customers as these that the trade of the importer depends in these days. Several other of the French raisers are well represented. Very pretty indeed, in some cases absolutely charming, novelties may be discovered amongst the new things of 1898, but their merits in this respect are overshadowed by their want of size, and therefore they will hardly be noticed by most of the big bloom admirers whose name is legion, and whose opinions seem to be final in adjudicating upon the novelties of the season. Of late years M. Ernest Calvat has made rapid strides in the supplying of such new Chrysanthemums as are now fashionable, so much so that there is hardly anyone of his fellow-countrymen that seems able to compete with him. Many of his flowers occupy, and will undoubtedly continue to occupy, a foremost position on the show-boards, and those of this season form no exception to the rule. Among recent novelties from this raiser, Messrs. Cannell have on view M. Fatzet, a very large, deeply built Japanese incurved, close and compact and solid, colour rich golden yellow. Topaze Orientale is a lovely pale yellow incurved, of fine form, deep and regular in shape. Mlle. M. Expulson, a large white Souvenir de Holmes, is bright brick-red tinted and tipped with gold. In very rich shades of colour, Mme. Rob. de Massy is of a deep velvety purple with silvery reverse, a Japanese, large and deep in form. Le Grand Dragon, a fine Japanese of deep golden yellow, has already been mentioned in the National Chrysanthemum Society floral committee's report. Mélusine, very long drooping florets, white, shaded purple, is big and deep. Sardou is not large for an incurved Japanese: it has grooved florets of a reddish shade inside with reverse of gold. A fine yellow is to be found in Tatiana, which has long, drooping, narrow florets, and is of a beautiful shade of golden canary yellow. This promises to be quite an acquisition. Isrette, golden bronze; Président Nonin, Australian Gold, Beauté Grenobloise, white; Congrès de Bourges, Mme. Ferlat, N.C.S. Jubilee, a fine pale silvery pink; M. Massage de Louvrex, yellow; and the peculiar green Mme. Ed. Roger are all a season older than the preceding, but by no means the worse on that score. General Paquie is a very fine new yellow Japanese,

and from the same set comes Marie Calvat, a big white Japanese, slightly tinted. There are many other varieties from this source, but we have said enough to give an indication of their merits.

From other Continental sources a special note should be made of the white sport from Mrs. C. Harman-Payne called M. Louis Remy, the colour of which this year appears to be purer and better than when we saw it last. Mme. La Colonel Germer Durand is white, lined and streaked purple, and Mme. W. J. Budde, rather prettier than the preceding, a Japanese with long drooping florets, colour white, streaked rosy purple. Globe d'Or and Triomphe d'Ève are two of the old incurved type, and are fairly well known. Emile Nonin belongs to the same section, and is of a deep golden chestnut and distinct. Mme. Berlat is a Japanese incurved, very full and double, with narrow grooved florets: colour deep silvery lilac-pink. In the hairy section Leocadie Gentils seems to do well; the colour is very pale clear yellow, and a companion flower may be found in M. Piquemal de Rozeville, deep erimson with gold reverse. Yvonne Desblanes is another finely incurved continental variety, large in size and of excellent form, colour pure white. Ami Brouillet is of a very pretty shade of pale pink, and a choice little Japanese that does credit to its raiser. We might also briefly mention Mme. Fred Daupias, creamy white; Mme. Gab. Debric, lively flesh-pink; Mme. Bonnefoy, lilac-mauve, and several others. We are, however, not unmindful of the special claims of our kindred across the sea in far Australasia, and this is the first year we have had such a capital opportunity of seeing so many colonial novelties at once. Welike Mrs. J. T. Tibbs, a pure white sport of Lilian B. Bird, and also Mrs. H. B. Higgins, a fine large white Japanese of a pure creamy shade, very delicate and soft in tone. Mr. T. Carrington is a fit companion for such monsters as Australie and Pride of Madford, to both of which there is a slight likeness. Miss Mary Underhay is a Japanese incurved of very good build; the florets are of medium size, regularly incurved, grooved and ribbed on the reverse, a lovely thing in colour, being a rich buttery yellow. Purple Emperor, as its name implies, is grand, velvety purple and silvery pink reverse. Wonderful, of the Wheeler type; Euterpe, rosy mauve; Nellie Pockett, white; Mrs. Bissett, S. Kerlake, Jun., pure white, and Miss Vera May Fraser, lovely shade of terra-cotta, exhaust the space at our command for this group. Among home-raised Japanese of varying shades of yellow, Edith Tabor, Ella Curtis, Baron Tait, C. F. Payne, and the fine Carnot sport Mrs. W. Mease must not be forgotten. Lady Hanham, the beautiful Vivand Morel sport, is also first-rate; and in whites we get Mrs. H. Weeks, Lady Byron, and Kathleen Rogers, a Japanese incurved of good size and substance. Swanley Giant is big and solid, a Japanese incurved of deep rosy pink. Then Mrs. A. Cross, somewhat similar in build, but of a deep golden yellow, is a rather large bloom, but of these we have enough and to spare.

American novelties are not numerous, but most of the older sorts are well done, and are already in general cultivation. New pompons and Anemone sorts seem also to be almost wholly neglected, while the Japanese and incurved sections alone seem to engage the attention of the raisers.

Chrysanthemum Sœur Melanie.—This excellent second early variety has now been many years before the public, but I question if there is a more useful kind in cultivation for outdoor flowering, for under the most rough-and-ready system of culture, such as is accorded to ordinary market flowers, it produces a wealth of bloom that is really astonishing. I have at the present time some old clumps that have stood in the same position for three years, and have spread out into great circular patches. During the intense drought that prevailed up to the end of September they looked as if they would be quite dried up, but directly rain fell they began to revive, and are now completely covered with finer blooms than

those of the same variety grown in pots. This variety when first expanded has a decided pink shade, but soon turns to a pure white; in fact, if placed under glass it soon becomes one of the purest of white varieties, well adapted for wreath making. It is also especially suited for open-air culture, as it sends up abundance of shoots

upon them, but a defect of many is that they have quite semi-double flowers; hence they lack that charm which is so perceptible in true singles. Generally flowers that have two or three circles of petals pass muster if they have clean, bold eyes or centres, and if these be lacking, a little pulling of objectionable petals soon puts them right.

CHRYSANTHEMUM NOTES.

As regards novelties, the present season promises to be of more than ordinary interest. A novelty, to find ready acceptance by growers generally, must possess some distinguishing characteristic—the form of the flower or its colour, or the ease with which it can be produced in good form, and perhaps its height; each point is a commendation, and assures for it a trial for one season at least. The present season's novelties in many instances are represented by flowers of high quality.

The varieties introduced by M. Ernst Calvat this season are of a high order of merit. One of the first to flower was *Le Grand Dragon*, an immense Japanese bloom, with very long and pointed petals of medium width, of a deep rich yellow colour. Like many of this raiser's varieties, this plant is one of easy culture, and also succeeds well when propagated late and flowered on single stems in 6-inch pots. *Mme. Couvat du Terrail* should also prove a fine addition to the Japanese, early flowers developing cream-white, passing to white with age. The petals are very long, prettily eurred at the ends. The blooms are developed on long, stout foot stalks. In M. Fatzer we have one of the most promising of this year's set, and this appears to succeed very well under the orthodox treatment. In 6-inch pots the blossoms open kindly and are of large size, with long petals of medium width and splendid substance, slightly twisting and incurving at the tips. The colour is a distinct shade of deep canary-yellow, with a paler reverse, and the flowers when finished make splendid exhibition specimens. The height is about 4 feet. Other good sorts from the same source are *Mrs. T. A. Compton*, white, shaded lilac; *President Bevan*, a lovely buff-yellow and of considerable promise; and a superb soft rose variety named *Marie Calvat*, opening somewhat earlier than some of the others.

From other sources we have a lovely straw-yellow sport from *Mrs. W. H. Lees*, and, knowing the value of the parent variety as an exhibition flower, it is pretty safe to state this new sport will be in large demand. *Madeline Davis* may be described as a silvery white, tinged throughout with rosy violet, this colour deepening at the edges. In shape the bloom is not unlike *Phobus*, but with longer, broader, and more tapering florets. *Rayonnante*, exhibited at the recent October show of the National Chrysanthemum Society, is rather unique in form and colour. The florets are very long and stiff and of a pleasing colour of deep flesh-pink. The flowers are of immense size, and are developed on plants about 5½ feet high. A handsome flower is *Mr. F. Brewer*, said to be a seedling from *Viscountess*

In the grounds at Strathfieldsaye, Hants. From a photograph by Mr. F. Mason-Good. (See p. 405.)

from the base and is not liable to die off during winter or spring.—J. G., Gosport.

Single Chrysanthemums.—A very successful grower and exhibitor of these pretty flowers finds it is not difficult to save seed and raise his own plants; hence he usually exhibits in a box of twelve varieties quite half of his own seedlings. There are so many of these singles under name in commerce that it may seem difficult to improve

Still, none excel those which produce flowers devoid of imperfection. For home decoration of any description, none of the Chrysanthemums excel the singles for grace and elegance. The flowers well repay moderate disbudding, because they are then so much finer and more perfectly developed. It is but needful to observe a box of good blooms gracefully set up to realise how charming they are for cutting.—A. D.

Hambledon, with broad petals loosely incurving; colour deep golden yellow, paling towards the edges, with a pale straw yellow reverse. Soleil d'Octobre, although introduced last season, has been exhibited in fine form; it is of a lovely canary-yellow colour. Another October sort is Mrs. A. Cross, a rich citron-yellow, and a fine full flower; the florets are long, broad, prettily twisted, and the habit is dwarf. Mme. Louis Remy, the white sport from Mrs. C. Harman-Payne, early in the season was anything but a pretty white, but later buds are new developing blossoms of the purest white and free from much of that coarseness which usually characterises the flowers of this type. The long-looked-for pink sport from Mme. Carnot has at last appeared. The blooms are now fast opening and the florets are of the desired colour. A flower very much resembling in colour E. Molyneux is said to be a sport from the once popular President Borel. As seen, the blooms are very taking, and as this is a plant of easy culture, it is safe to assume it will be a popular kind. A graceful spreading flower is Mrs. L. Humphrey, which opens somewhat similar to a yellow Chas. Davis, but with a deeper-coloured centre, the exterior of the bloom being a lovely straw-yellow. The length of the petals is remarkable, and these are forked at the ends. The plant is rather a weak-growing sort, and usually attains a height of about 4 feet. Joseph Chamberlain is opening most kindly, its bright glowing crimson florets with golden reverse making a striking flower.

There are two or three earlier deserving special notice, the first of these being a lovely soft yellow sport from Queen of the Earlies. For market work and for early conservatory decoration this is sure to be largely in demand. Crimson Marie Massé is also a fine addition, and those who know the freedom of the parent variety will at once appreciate the value of this bronzy crimson sport. Louis Lemaire, the bronzy red sport from M. G. Grunerwall, is an acquisition, and an ideal plant for August and September displays. Of May Manser, the ivory-white Japanese, too much cannot be said. This variety should out the once popular Mme. C. Desgrange. D. B. CRANE.

CHRYSANTHEMUMS AT EARLSWOOD.

LAST season Mr. W. Wells, of the Earlswood Nurseries, Redhill, certainly had the finest, if not the largest, trade display in the vicinity of the metropolis; and we were therefore not at all surprised to find that his present show of the popular flower is in every way up to his reputation. The collection is housed in a very large glass structure something like 150 feet by 25 feet, having a large central bank with two faces, together with a border round the sides. Most of the plants belong to the Japanese section and are of quite modern introduction, a striking and interesting contrast to the displays in the parks, for the visitor is constantly coming across something new and novel to arrest his attention. Very fine in the Japanese incurved class is Mme. Desblanc, with narrow pointed florets, globular in build, and of a lilac-mauve colour passing to white. Souvenir des Norgiots is a Japanese Anemone of a rather peculiar shade of cinnamon-buff with a centre of deep yellow. We noticed, too, that the pale yellow hairy novelty, Leocadie Gentils, is coming very good, and amongst other novelties from miscellaneous sources Mme. Gabriel Debrie, pure pale flesh colour, a big Japanese incurved, and a very delicate colour, is likely to be heard of again. Purple Emperor, a lovely velvety purple Japanese of Australian origin, will make a worthy companion for some of the other introductions from Great Britain over the sea, a special note of which we may give somewhat later in the season. Princesse Hélène is a Japanese with very long drooping florets, a great favourite with the French exhibitors, colour pale creamy white, and quite as good as we have seen it on the Continent. A very beautiful soft pale yellow incurved is found in Topaze Orientale,

and Yvonne Desblancs is another pure white and of perfect build. Emile Nonin, deep golden chestnut, also belongs to the same section. Fairly well-known novelties that are well done and need only a passing mention are Simplicity, Mme. Carnot, Mrs. J. Lewis, Mme. Ph. Rivoire in whites. Then there are some very good blooms of G. J. Warren, the yellow Carnot spot, and the pale sulphur Mrs. W. Mease, which claims the same parentage. Lady Hanham, the Vivand Morel sport, and Mrs. J. W. Barks, a fine deep golden-bronze sport from Edith Taber, are both worthy descendants from popular favourites. Mary Molyneux, pale silvery pink, large and promising, was seen last season in very grand style. W. Towers, with medium-sized narrow florets, pale canary-yellow; Ella Curtis, deep golden yellow; and Mrs. Hunter Little, with long narrow florets, but rather thin, were also attractive. Mrs. G. W. Palmer is a rich purple-bronze, and M. Louis Remy, a pure white, are sports from Mrs. C. Harman-Payne and equal in size. Joseph Chamberlain is deep chestnut-crimson, reverse golden, very compact, and of the incurved Japanese type. Of Calvat's seedlings, Mme. G. Bruant, introduced last season, is richer in colour than we have seen it elsewhere, for instead of being almost white it is of a fine shade of pale purple-mauve, paling off to white in the centre. N.C.S. Jubilee, delicate silvery pink, is good. Surpasse Amiral is a large deep golden yellow. Dr. Liébert is another large one, having narrow florets curly at the tips, pale pinkish mauve. Iserette is also good in colour. M. Hoste, President Nonin, Werther, Mme. Gustave Henry, Congrès de Bourges, Mme. Ferlat, Australian Gold, the very curious green Mme. Ed. Roger, and Mlle. Lawrence Lédé, all recent introductions, have already been seen in more or less good form last season or before.

But dealing exclusively with his novelties for the present year which have not been seen in flower in this country before, the most meritorious in his set are undoubtedly President Bevan, a fine large solid Japanese incurved, with broad florets, colour deep golden buff; Mlle. Madeleine Expulsion, a deeply-built bloom, with florets sharply pointed, twisted and intermingling, colour pure creamy white; Marie Calvat, a very large, but rather rough Japanese, with long straggling tubular florets, white, tinted purple; M. Fatzer, Japanese incurved, with medium florets, deep golden yellow, outer florets tinted bronze; Mme. Couvat de Terrail, large, but flat, a Japanese, colour white, and General Paqué, a fine Japanese, with flat drooping florets, colour deep golden amber, with golden reverse, and of which a coloured illustration was given in M. Calvat's spring catalogue. Mme. Bertet, white; Melusine, rosy white; Mlle. Gab. Seince, white, also belong to this season's set, but are not so striking and effective as those already named. We ought not, however, to leave this eminent grower's novelties without referring to Le Grand Dragon, a fine long-petalled golden yellow Japanese; Tatiana, a very close compact Japanese with long drooping florets, a finely-formed flower, colour rich canary-yellow; and Perle, a large Japanese with long quilled florets, a pleasing but curious flower, colour deep lilac-pink. There are in all thirty-two of M. Calvat's 1898 novelties, but we think we have selected from them the names of the best and those most likely to suit the exigencies of English exhibitors, to whom M. Calvat appeals far more than most of his fellow-countrymen. Mrs. White Popham is a very large, deeply-built Japanese flower, with medium sized florets, pointed at the tips, colour pale purple-mauve and a silvery reverse. This is grown in large quantities and makes an imposing-looking bloom. A fine deep golden chestnut tone is found in John Pockett, an incurved Japanese of colonial origin, having rather broad florets and a reverse of golden bronze. Pride of Madford, from the same source, also appears to maintain its previous reputation, while the rich crimson sport from that variety, Pride of Stokell, having a golden reverse, streaked crimson, will be effectively employed where

brilliance of colour is required. Also of colonial origin are Australian Belle, a deep rosy pink, and a large white called Mrs. C. Bown. Chatsworth is another, but the finest of all is undoubtedly Mr. T. Carrington, a Japanese incurved, with very deeply grooved florets, pointed and of great length, the colour being deep velvety purple, with a reverse of pale silvery purple. Still confining our remarks to Australian seedlings, in which the Earlswood collection is peculiarly rich, Miss Nellie Pockett, a fine white Japanese, has been seen in good form at several places, and The Convention, Japanese incurved, deep golden terra-cotta, shaded bronze inside, is of a very taking shade. Mrs. G. A. Harris, golden bronze, is striking, but rather small; and certainly one of the finest, which, we believe, it is intended to call Lord Ludlow, has a multitude of narrow grooved florets of great length, is very deep and globular in build, and in colour is of a very rich shade of fine canary-yellow, shaded in some instances with bronze.

THE MARKET GARDEN.

CARNATIONS FOR PROFIT.

THOSE who can grow Carnations well, keeping up a regular supply of perfect blooms, say, from October till May inclusive, need never despair of finding a market for them. As a matter of fact no other flower, if we except double Violets, sells so readily, while the prices, which range from 1s. to 2s. per dozen for medium-sized to large flowers, must be regarded as satisfactory. Nor is there much likelihood of the market ever being overstocked, only a comparatively few succeeding well with Carnations. Personally, I fail to see anything very difficult in their cultivation. Rooting the cuttings seems to be the greatest drawback, and seeing that only young plants are sufficiently and constantly free-flowering to pay, failing to root cuttings may be the principal cause of so many market growers commencing to grow Carnations only to give them up again. Soft cuttings sent me from private gardens have failed to strike, but any slipped from plants grown in the full light of a market grower's house rarely fail. They must be young, short, and firm. Slipped out of their socket, the base split, duly inserted round the sides of a 4-inch pot filled with equal parts fine loam, leaf-soil, and sharp sand, placed in a brisk heat any time in February or March, and kept close, very few fail to strike root with me. Late summer and autumn propagation is also desirable, the cuttings rooting readily in a gentle heat if shaded from direct sunshine and not kept too close or moist. Some of the finest stems of blooms of William Robinson I have yet seen were produced last spring by plants rooted during the summer of 1897. They were not topped, grew to a height of 3 feet, and produced grand blooms, each borne by a stem 6 inches to 9 inches in length. Other varieties I grow, including Reginald Godfrey and Duke of York, succeed well under similar treatment, all being flowered in 6-inch pots. Late autumn-struck cuttings, kept during the winter in store pots, are of good service for growing to a large size or for flowering in 8-inch pots the following season. Layers rooted in August are good for flowering the following spring, those detached from plants in the open ground frequently producing profitable heads of bloom.

It is of the greatest importance that the young plants all through their career be kept quite free of insect pests, notably green and black fly and red spider. The presence of the two former is easily detected, and the effect of their action on the young unfolding leaves

unmistakable. If kept free of aphides when in a young state by occasionally subjecting them to nicotine vapour, following this up all the time the plants remain under glass, there will not be much trouble at other times. Red spider does not attain, as a rule, full size on Carnations and is not easily seen without the aid of a lens, but the leaves soon show the effects of its presence by becoming yellowish in colour. This season is most favourable to the spread of red spider, and if Carnations are, in the course of the next few weeks, arranged for the winter on dry shelves without any attempt being made to clear them of red spider, trouble will be in store. I am no advocate of the treatment recommended by so-called experts, who seem to think disease can only be warded off by keeping the plants on raised stagings and the foliage and atmosphere of a house as dry as possible at all times. During the hot weather of August and early part of September my plants have been frequently syringed, also forcibly sprayed with clear water through a hose, and if that is not enough to keep red spider under, all the plants will be well syringed with water to which flowers of sulphur has been added at the rate of a good handful to a three-gallon can of water.

POTTING.

Over-potting, coupled with the employment of a too close or too rich compost, is another cause of failure. Carnations revel in good leaf soil and also like sandy, clayey loam. Root fibres can be dispensed if only the loam is not too rich or clayey. Fibrous loam is too great a luxury for the growers of pot plants by the thousand to think of, and not a single bushel of it is used here. My Carnations root surprisingly well in a mixture of two parts loam to one each of leaf-soil and "burn-bake," soot water with an occasional surfacing of native guano doing the rest. The drainage ought always to be good and the potting be done firmly. It is possible to err on the side of using too small pots. The bulk of my winter-flowering plants is in 7-inch pots. Not till they are well established in these, their flowering pots, is a portion of the plants removed from shallow pits and frames and arranged on ashes in a sunny sheltered place. The lights are removed from the rest, and these left where they are till housing time. Topping will be alluded to when the merits of different varieties are discussed. Staking consists in placing a single stake to each plant, securing the leading growth or growths to these before they fall about the pots and become crooked. About the middle of September is a good time to house the plants, the prospect of much rain with its saturating effects upon the plants hastening operations. They are not arranged on a dry staging, as I find Carnations thrive better when stood either on an ash-covered slated staging or on the solid ground—in either case not far from the glass—allowing head room of 2 feet to 3 feet, according to the habit of the varieties, *Thérèse Franco* and *Winter Cheer* being the dwarfest grown by me. From the time the plants are housed till the spring they have to be carefully watered, and must not be left to the tender mercy of careless labourers or reckless boys. They are not allowed to become quite dry at the roots, and when they are watered a soaking is given. If the foliage is not sufficiently green to please me, either a light surfacing of native guano—a mild and safe manure that the roots come up after—or soot water is applied, a change for the better soon being observable. Enough warmth is kept up in the hot-water pipes to exclude frost and to prevent a cold, damp feeling striking anyone on going into the house—a

long span-roofed structure—but anything approaching a fixed temperature is not attempted. A genial warmth, no forcing, all the light possible, with a little top air on mild days appear to suit Carnations well all through the duller months of the year. Disease once broke out on one variety only, but none of it was met with last season, thanks to well coating the affected leaves with moderately strong lime water. It must be understood that I am not growing many *Mahmaisons* for the very sufficient reason that other varieties pay better—at least such is my experience.

PROFITABLE VARIETIES.

When I first commenced growing Carnations on a fairly large scale my first aim was to find out what varieties succeeded best under the somewhat rough-and-ready methods of culture, and also which florists found most in demand. "A good white Carnation always sells well," remarked a friend; and so it does, though sometimes at lower prices than are given for, say, a good pink variety. It will answer no good purpose giving the list of partial or complete failures, especially seeing that some of these are strongly recommended by men who have quite as good reason to write in glowing terms of them as I have of the varieties shortly to be commented on. Uncle John, originally introduced, I believe, from America, is my favourite white. The plant is somewhat thin in growth, but if not topped more than twice, and that early in the summer, the stems flower grandly, mine, owing to the great heat, having already commenced. All being well, I shall be able to cut a few or many dozen blooms, according to the time of year, every week till June next. The flowers are moderately large, pure white, do not burst their calyces, can be cut with long stems, and, in common with most fringed-petalled varieties, are sweetly scented. *Reginald Godfrey* is an equally good pink variety, or the best in the section. The plant is of tall, robust growth, the stems branching and flowering freely; the blooms are large, very double, not much given to bursting of calyces, pale pink in colour, and sweetly scented. *Thérèse Franco* I also grow, but it is not so profitable as *Reginald Godfrey*. The plant lacks vigour, not forming flowering stems tall enough and sufficiently stout to please me, but I can always find flowers on the plants, and these are moderately large, flat, bursting occasionally, while the colour is a pleasing salmon-pink. Newer varieties of yellow flowering Carnations, notably the clumsy *Primrose Day*, have been most disappointing. I have cleared them all out, and now appreciate *Germania* much more than formerly. Unfortunately, it cannot be rightly termed winter flowering, but by a little management blooms can be had of it nearly all the year round. Young stock obtained by layering growths on border plants in August and placing in 5-inch pots in September or later flower grandly the following April, mine last season scarcely producing a faulty bloom, and it is these plants that should during the summer be shifted into 7-inch pots, larger if extra strong. Mine thus treated are already giving a few acceptable flowers, and I hope to have large numbers during the winter from the stems now developing.

Dark crimsons are always in good demand, and *Uriah Pike* was to be a small gold mine. This, again, is a border variety, and is only a shade better than good stocks of the *Old Clove*. Treated as advised in the case of *Germania*, my old plants produced a short crop of comparatively small blooms, and the young ones a glut for a few days in the spring. So little do I care for it that none will be housed this

autumn. *Duke of York* is by far the finest dark crimson variety that I am acquainted with. What must be regarded as a drawback to this sort is its lanky habit of growth. It must be grown tall and strong, or no flowers will be produced before the spring. Topping spoils the plants. Let each plant grow unchecked, and by the end of August the majority will be 30 inches high and well furnished with flower-buds, these opening slowly, and a few blooms are available all through the late autumn, winter, and spring months. Late-struck plants, as previously intimated, flower well in the spring. The blooms of *Duke of York* are large, not very double, rarely burst, rich dark crimson in colour, and scented. A good scarlet was not so easy to find as might have been anticipated. *Winter Cheer* is not quite robust enough, but after the plants are housed they usually improve rapidly, pushing up moderately strong, slightly branching flower-stems. The blooms open regularly, are somewhat small, of good form and colour. *W. Robinson* was at first disappointing, and I did not like the appearance of the long, naked, that is to say, branchless—stems. The late-struck plants were not topped, and these, growing to a height of 3 feet, produced large, handsome, non-bursting, rich scarlet blooms on long stems in the spring most profusely. Such plants are not much to look at, but I liked them so well that only a very few of the early-rooted plants have been topped this season, and very promising all are at the present time. W. IGGLDEN.

NOTES ON PEAS.

THE best Peas for early use I find are *Chelsea Gem*, *May Queen*, and *Dickson's First and Best*, to be followed by *Gradus*, *Duke of Albany*, *Dr. Maclean*, *Veitch's Maincrop*, and for an autumn supply, *Maclean's Best of All* and *Autocrat*. For an autumn supply, *Autocrat* should be sown not later than the second week in June, as it gives a supply for a long time; *Maclean's Best of All* should be sown about June 25; and *William Hurst* or a good early sort the first week in July. —J. HAMMOND, *Tenyrith Manor, Woburn*.

— I find *Chelsea Gem* the best sort both as regards quantity and quality. I grow this variety for early and late use. For the early picking I try to get the seed sown at the end of January or early in February, as opportunity permits. If I find the weather against sowing at that time I generally have the amount of seed Peas which are to be sown laid loosely and thickly in some boxes, mixed with some damp soil, and stood in a greenhouse for a week or so to start germination. I find this plan a good one. My main-crop Pea is *Autocrat*. I find none to equal it both as regards constitution, quality, and good cropping qualities. I also grow *Veitch's Perfection*, *Barnet Hero*, *Ne Plus Ultra*, *Duke of Albany*, and *Stratagem*. *Veitch's Perfection* I find very good, but *Duke of Albany* and *Ne Plus Ultra* Peas do not, as a rule, do well with me. For a late crop I like to sow *Chelsea Gem* about the end of June or beginning of July, following an old *Strawberry* bed as soon as the fruit can be got off. I should recommend *Chelsea Gem* for early, *Autocrat* and *Veitch's Perfection* for main crops, *Chelsea Gem* and *Autocrat* for late. *Autocrat* does not take mildew in the autumn as many varieties do. —H. MORRIS, *Barham Court, Maidstone*.

— For earlier sorts I use *Veitch's Selected Early*, *William L.*, and *Gradus*. *Early Morn* is a fine early sort, of good flavour. For second and general crop *Criterion*, *Maincrop*, *Ne Plus Ultra*, *Telephone*, *Dunby's Stratagem*, and *Veitch's Perfection* are sorts which have done well here. For late crops *Autocrat*, *Ne Plus Ultra*, *Chelsonian*, and *Maclean's Best of All* are good sorts. For autumn supplies *Ne Plus Ultra*, sown April 25, comes into use August 20 to 30; *Ne Plus Ultra*, sown May 5, in use August 25 to September 10;

Chelsonian, sown May 5, in use August 25 to September 10; Telephone, sown May 14, in use September 1 to 15; Autocrat, sown May 14, in use September 5 to 25; Autocrat, sown May 26, in use latter half of September; Veitch's Perfection, sown May 26, in use latter half of September.—D. MELVILLE, *Dunrobin Castle Gardens*.

— A small sowing is made of Veitch's Extra Selected Early. This is followed by Chelsea Gem, Gradus is sown next, Duke of Albany follows, with Criterion and Autocrat for a main crop. Autocrat is relied upon for the autumn supply. If limited to one variety I would select Gradus for first early, Criterion for midseason, and Autocrat for autumn. My last sowing is made of Autocrat about June 15. This sowing keeps up a regular supply until frosts appear. A sowing of this variety made on that day last year kept up a regular supply until November 6. On that morning we had a sharp frost and a thick fog for several days afterwards, which checked a supply that appeared promising for another three weeks.—GEO. H. MAYCOCK, *Luton Hoo Gardens, Luton, Beds.*

— The only dwarf I depend on is Chelsea Gem, which crops here better than any other, being early and of good flavour. The other earlies depended on are William I. and Exonian, both of fine flavour and cropping freely. Duchess is a most prolific kind, fine in pod and flavour, followed by Alderman. A fine all-round Pea next in gathering is Ne Plus Ultra, followed by Autocrat. Walker's Perpetual Bearer, though likely a near relative of Autocrat, I find is distinct in growth and time of coming in. I finish up with Omega. These carry us on till frost generally puts an end to them often in November. I never sow early Peas for a late crop. Exonian and William I., left standing for the protection and shade of plants standing between them, often produce a good second crop. Other varieties grown are The Don, Empress, Sharpe's Triumph, Bliss's Abundance, and Alfred the Great.—GEORGE BOLAS, *Hopton Hall, Wickswoth*.

— The two best early Peas this year were Veitch's Chelsea Gem as a dwarf, and Sutton's May Queen, 3 feet to 4 feet. I still grow the free-cropping William I. for an early supply. Webb's Senator is a fine 3 feet high Pea, and an abundant cropper, Peas large, well filling the pods. Duke of Albany is a favourite second early which I grow in quantity, the flavour being very good and Peas of a fine colour when cooked. After these I rely chiefly on Autocrat, Chelsonian, Ne Plus Ultra, and Goldfinder, a selection apparently from the last. Autocrat and Ne Plus Ultra are two of the best I know for a late supply, resisting mildew attacks better than many other kinds. These two are sown in quantity about the middle of June, and a few a week or so later for the late supply. Both invariably supply pods well into late autumn. One of the worst enemies I have to contend with are the small tits, which are particularly fond of Peas in autumn, and netting has usually to be used to protect them.—C. HERRIN, *Droptmore*.

— I still hold to selected William I., because the returns are so much more than from the dwarf kinds if sown at the same time as William I. Gradus follows. This I consider a grand Pea as regards flavour and cropping. I then follow with Telephone, Telegraph, Duke of Albany, and Duke of York, all good reliable Peas. For the latest sowing I prefer Ne Plus Ultra, Walker's Perpetual Bearer and King of the Marrows. Another good Pea I can strongly recommend as a good second early Pea is Peace and Plenty, sent out, I believe, some four years ago. As regards time of sowing for late crops, much depends on the season. I have sown on the same date for several years. One year you get a good return, the next none, but I never care to sow after the end of May.—T. LUCAS, *Strachy Castle, Llanelli*.

— Peas are a formidable quantity, so many sorts being really good and worth growing. One point in connection with many large-podded Peas is worth noting. It is this: they take a very much longer time to fill than smaller-podded

varieties, and it is worth while to expedite filling by removing the tips of the shoots when enough bloom is apparent to produce a full crop. Really good Peas are Chelsea Gem, The Prior, Stratagem, Boston Unrivalled, Critic, Epicure, Gradus, Veitch's Perfection, Autocrat, Ne Plus Ultra, Fame, Telephone, Michaelmas, and Dr. Maclean. Chelsea Gem as an early; midseason, Boston Unrivalled, Stratagem, The Prior; and for late; Fame, Autocrat, Ne Plus Ultra, and Michaelmas I consider the best. For late crops I sow from the 7th to the 11th of June; Michaelmas on the earlier date, Fame on the later. By pinching the growths at different dates a better succession may be secured.—R. P. BROTHERSTON, *Tyningham*.

— The best twelve varieties of Peas are Chelsea Gem, May Queen, William I., Duke of Albany, Prodigy, Telephone, Mainerop, Marrowfat, Champion of England, Ne Plus Ultra, Autocrat, British Queen, and Latest of All. I consider the best early varieties are Chelsea Gem, May Queen and William I.; the best midseason, Duke of Albany, Prodigy, Mainerop, Marrowfat and Telephone; and the best late varieties, Ne Plus Ultra, British Queen and Latest of All. Chelsea Gem is especially adapted for forcing. I gathered several grand dishes of it last Easter. The earliest I have gathered it outside is May 28. I always sow the second and third weeks in June for latest supply, and have always been fairly successful in obtaining a good crop.—F. W. GALLOR, *Theobald's Park, Herts.*

— The Peas I find do best here are Chelsea Gem, English Wonder and American Wonder. These sown from the middle of November to December 1 always do well with me when the season is fairly good. I am very partial to the dwarf varieties, especially those named, as I have pulled quite as many Peas from them as 6 feet high ones, and they save all the expense and labour of rods. If we could get a dwarf Ne Plus Ultra it would be invaluable. It is difficult to say which are the best Peas for cropping and flavour, as they vary very much. This I attribute to the season. As a rule, Duke of Albany, Stratagem, Dignity, Sharpe's Queen, Telegraph, Veitch's Perfection, Dr. McLean, Premier, Criterion, Sturdy and Ne Plus Ultra are the best. Mr. Gladstone promises to be good. Duke of Norfolk is going to be a grand Pea, a good grower, with large pods, nice and ten in pod, and of good flavour. For late work I make two sowings in July, and if the autumn is favourable I get good returns.—A. HENDERSON, *Thoresby*.

— The Peas I consider best with regard to cropping and flavour are Knowfield Early Marrow, Gradus, Boston Unrivalled, Alderman, Duke of Albany, Duchess, Sharpe's Queen, Ne Plus Ultra, Captain Cattle and Laxton's Omega. The best early variety undoubtedly is Gradus, which bears large well-filled pods with Peas of excellent flavour. Other varieties may be had a few days in advance of it, but if limited to one I would give the palm to Gradus. For midseason, Boston Unrivalled, Sharpe's Queen and Veitch's Perfection are the best I have tried of the 3-foot section, Alderman and Duke of Albany the best of the taller varieties. For late supplies Ne Plus Ultra still holds foremost place, but from what I have seen of the new Pea Captain Cattle, which grows about 4 feet high, it bids fair to become a favourite for autumn use. For a good late dwarf Omega is hard to beat. Sowings for an autumn supply should be made about the middle of May and again in the first week in June. The last-named date will, to obtain a good crop, be found quite late enough for this part of the country.—JAMES HILSON, *Narworth Castle, Carlisle*.

— The best early Peas in my opinion are Early Giant, Chelsea Gem and Sutton's Excelsior. I have had an experience this year that I have never had before, and that is Peas failing to set owing to the cold, dry, misty weather. Anything to do well here must have a very strong constitution. The second early Peas I consider the best are Empress of India, Royal Jubilee, Prodigy, Criterion and Veitch's Perfection. Of late Peas

I only grow one kind, viz., Chelsonian, which I consider is far away before any other. Sown in May this variety will give a supply of Peas quite late in September. The date for latest sowing here is about June 6. Then I generally sow a second early, or early. Prodigy and Criterion are two varieties that do well. I have gathered Peas into the middle of October if the autumn is fine from sowings on that date. The best Peas are Early Giant, Chelsea Gem, Empress of India, Excelsior, Royal Jubilee, Criterion, Chelsonian, and Veitch's Perfection, still a first-class Pea in every respect; for flavour it is hardly surpassed. JOSEPH CORBETT, *Mulgrave Castle, Yorks.*

— My favourite first earlies are William I. and Ringleader. These sown in the last week of January give first pickings end of first week in June. As second earlies I grow Telephone, Sharpe's Queen and Gradus; and for main and late crops, Ne Plus Ultra, Autocrat, Goldfinder, British Queen and Walker's Perpetual. The last crops are generally sown the last week in June in soil deeply dug and pulverised, the seed being sown in trenches prepared the same as for Celery. Our Pea crops of late years have been greatly pestered with thrips. I always mulch with long straw litter, which I am afraid is conducive to thrips, and shall be glad to have the opinion of other correspondents on this point.—W. SANGWIN, *Teddiesick, Truro*.

GARDEN FLORA.

PLATE 1197.

LILUM RUBELLUM.

(WITH A COLOURED PLATE.*)

No hardy plant created so much interest as this lovely Lily when exhibited for the first time at the Temple show held in May last. Rarely indeed is it we have to chronicle an absolutely new species from all points and possessing the rare beauty and merit of this one. Already this charming species has received more than a usual amount of attention, and its good qualities have been referred to on all sides. Best of all, perhaps, to those who give their chief attention to hardy plants is the ample evidence of the hardiness of the new-comer and the chances that it may become a feature in many Lily gardens in the future. In point of beauty it surpasses the chaste and exquisite *L. Kramerii*, to which on the first view it would appear somewhat closely related. But in its unique colouring it certainly does surpass this latter kind, and in the richness of the colouring has no rival in the widely-famed genus to which it belongs. Happily, too, it is a variable species, as witness the pleasing shades of deep pink or clear or deep rose, as the case may be, in none of which is there the least trace of washy coloration, a fact that greatly enhances the value of these slight variations in the plant. In a less degree, too, is the foliage variable. In the somewhat allied *L. Kramerii* the foliage is thin, narrow, and generally meagre, indicating probably a certain innate weakness of constitution, already well known as a fact. But in the lovely species now under notice we have a broader, stouter leafage, which indicates more or less the style and substance of *L. speciosum*. This is an especially true and striking fact with regard to the substance of the leaves, and if this semi-leathery touch is borne out in the life-history of the plant, then we have in the lovely new *L. rubellum* a plant that will indeed be a boon to our gardens.

If further proof of the general value of the species were needed, it is forthcoming from

* Drawn for THE GARDEN in Messrs. Wallace's nursery at Colchester by H. G. Moou. Lithographed and printed by J. L. Goffart.

a conversation with Mr. Wallace, Jun. This was to the effect that early in 1897 the firm received from Japan a quantity of collected bulbs, the majority of which came to hand in a badly shrivelled condition. The whole batch was at once planted, but as very few appeared above ground, it was considered the majority were lost. In lifting the good ones in autumn, however, a much larger number were found to be alive and making fresh basal roots. All the bulbs were immediately replanted, and many flowered the following summer. This is especially valuable information, because it happens almost invariably when a Japan Lily does not appear above ground during its year of planting that the bulb is dead. Of *L. auratum*, *L. Krameri*, &c., this is particularly true; therefore the two-fold fact of the bad condition when received and the subsequent recovery of the bulbs gave hopes of a better constitution generally. All this by subsequent experience has been proved. The coloured plate in today's issue speaks for itself, particularly in the unique colouring and the life-like manner in which the foliage is depicted. The plant, so far as is at present known, attains to about 2 feet high, producing three to five of its beautiful flowers on a stem, the blossoms emitting a delicate fragrance. A marked feature, as may be gathered from the coloured plate, is the great substance of the perianth segments and the distinctly rounded and somewhat obtuse divisions. Equally characteristic are the blunt and thickened buds, that give an impression of *L. Hansoni*, though only so far as size or shape is concerned.

The culture of this beautiful new Japan Lily, which is now reaching this country in great numbers, is very simple, the plants succeeding best in an open mixture of peat and sandy loam in equal parts, or, failing peat, two-thirds of good leaf-soil may be added. Too much moisture should be avoided till the roots are fairly active, and if grown in pots ample drainage should be afforded. But where it is intended to plant in quantity for cutting, it will be found the simplest way to prepare a small bed of a mixture similar to that already prescribed, planting the bulbs about 3 inches deep, employing plenty of sharp grit or sand about the bulbs. A slightly raised bed in a partially sheltered position would suit this Lily exactly, covering the bed with an inch or two of cocoa-nut fibre refuse should the winter prove severe. At the Temple show in May last, the floral committee of the Royal Horticultural Society unanimously granted this pretty species a first-class certificate. E. J.

Autumn tints.—There is a considerable loss of colour in the landscape this autumn compared with the past few seasons. To the great drought of the summer and autumn this is no doubt attributable. Trees of some kinds developed marked signs of distress weeks ago in the shrivelled and falling leaves where the ground was poor, thin, or heavily shaded by overhanging branches. Many Oaks showed this loss of leaf early, and the blackened foliage from the honeydew exudations has prevented the foliage presenting that natural autumn colour which bespeaks healthy maturity. The leaves, too, of many trees dropped early from want of root moisture. *Vitis inconstans*, which almost every year gives such a great depth of colour, is singularly deficient this season in a good many instances. On the mansion here this *Vitis* is a very fine feature, the colour developing so early in the autumn and so intensely bright. There are some spaces at the present time quite dull, and it cannot improve now at this late date. The common variety, on the other hand, has been even brighter than

usual where growing on wire arches, which is rather difficult to understand, because from a colour point of view the plants have not the same advantages as those on the house.—W. S., *Road Ashton.*

THE WEEK'S WORK.

KITCHEN GARDEN.

FORCING ASPARAGUS.—To keep up a supply from now to the end of January I find it necessary to lift the roots. I am not much in favour of lifting, as the plants after being forced are useless, and as they take years to grow, it is an expensive process. It is useless to lift weak plants, as the produce will be poor. Many growers find it best to lift an old bed and to make a new one annually, as the older plants force readily and give a better return. Roots that have been cut over for years can be lifted, and there is a gain in some soils, as the roots may have got down into poor soil, and by making new beds one can give the land better cultivation. Those who grow young roots for early forcing will find this mode of culture the most profitable, for the return from such plants will be good. This is a system I would advise where large quantities are needed and there is land to grow the plants for the early supply. Forcing is easy, the chief points being to give just sufficient warmth to start the crowns into growth; excess of heat means weak growth and loss of flavour. I prefer a heated frame, as this allows the plant to be a short distance from the glass and prevents the growth drawing. The roots at this season will need a gentle bottom-heat. I find leaves and stable manure the best, as the leaves give a gentle, lasting heat, and, what is so essential, moisture, which the roots delight in. If large quantities of stable manure are used, the heat at the start is too violent. The top-heat need not be more than 60°, and in mild weather I use very little warmth in the hot-water pipes, and at night the glass is covered. To keep up regular supplies from this date, it will be well to introduce plants into the frames or pits every three weeks, and in quantity according to the demand. When the growth appears above the soil it will be well to syringe or water with tepid water. Very little top soil is necessary when placing the roots in the heating materials. It is well to make the beds firm to retain the warmth and prevent sinking. The roots may be placed quite close to each other, giving tepid water when starting.

FORCING PERMANENT BEDS.—This is one of the most profitable modes of forcing Asparagus, but unless the grower has the best material at hand, I find it well to reserve the permanent beds for the supply after the new year is in. Some growers have modern appliances, and with hot-water pipes or heated flues under the beds they can get earlier supplies, but even then it is not a profitable proceeding, as the beds to give a good return need a longer rest, and force more readily at the season named. At the same time if the beds are forced yearly they will soon respond when warmth is applied, but the top growth with shortening days and little sun-heat is not equal to that two months later. I now commence to force our permanent beds for late January supplies, and to give the produce for use from then till the open ground beds come in. Having little fresh manure to spare I use large quantities of fresh leaves, which are valuable, as, though the plants are much longer in starting into growth, the produce is superior. The beds are 4 feet deep with a width of 3 feet between each. This space is filled with the leaves. I find it best to gather the leaves and place in a large heap before putting the same into the 3 feet spaces, as this allows of the leaves being trodden more firmly than if put in as gathered. In November or early in December, as soon as sufficient leaves are procured, I make up the beds for forcing, and as the materials sink more are added and made as firm as possible. This creates a gentle heat. The chief thing

afterwards is to ward off snow and heavy rainfall. To prevent this the leaves are much higher than the beds, and long strawy litter is used as a top covering. Shutters or frames may be used directly over the beds. I use frame-work bolted together and boards for covering. A little warm litter is placed over the surface soil of the beds when the leaves are heating freely, and in severe weather long litter is placed over the shutters and heating materials also. From beds treated thus there will be grass equal to that grown in the open. Of course, early in the season it will be blanched, but grown in this way the flavour will be good and the cost of production trifling. The old heating materials are valuable, as these when cleared out will be most useful for many purposes, and as I irrigate the forcing beds in the summer months with liquid manure the decayed leaves are of greater value.

SEAKALE FORCING.—This may be had in quantity from now to April, and at this time of year it will be found of better quality if forced so that the top growth is not drawn. To get good Kale at the end of November a brisk heat must be employed, and though, as I have stated, Seakale can be forced easily, it is essential to grow it in the dark and with enough moisture to make it palatable. A Mushroom house is the best place if the house is heated, but the roots should have the warmest corner. At this time of year I place the roots over the pipes with a good depth of leaf-soil under and several inches over the roots, and give tepid water when watering. Other ways equally good may be adopted. Many force in deep boxes with great success, and I have seen splendid results follow burying the roots more deeply. Of course, grown thus, the moisture must be sparingly supplied. For regular supplies it will now be well to place roots in their forcing quarters every ten days or a fortnight, selecting the strongest roots for the earliest supplies. Avoid rank steam, which soon spoils the blanched tops, and strong heat affects the quality. More warmth will be needed for the first lots at this time of year, as the roots have had no rest. I do not advise forcing with pots and manure in the open at this early date, but growers may with advantage use slower heating materials. The best Kale I ever saw was obtained from plants covered over in December with boxes, leaves to the depth of 4 feet being placed over them and made as firm as possible. This gave splendid heads in ten weeks from the time of covering the beds. In a severe winter it would be necessary to give a greater depth of heating material or use litter over the leaves. Those who need large quantities of Seakale by a certain date may with advantage adopt the market grower's mode of forcing. The roots are lifted, trimmed, sorted into sizes and placed in wide trenches a foot to 18 inches in depth. Over this is placed strawy litter and on the litter a good depth of fresh manure. This of course heats quickly and needs frequent testing. If the heat is too violent, more litter is added. At the same time there is a danger of steam injuring the growths if it does not escape. Another mode of culture is to place the Kale on manure and cover over the crowns.

FORCING RHUBARB.—This will be useful for tarts and other purposes towards the middle of December. I find the small red kinds, such as Royal Albert or Early Red, the best for hard forcing. Johnston's St. Martin's and Myatt's Linnaeus are also very reliable for first supplies. At this date more warmth will be needed to get produce freely for mid-December and later use. I grow specially for this purpose by sowing seed in frames early in the year and then growing on in a rich soil on a warm border. The roots are of a nice size for forcing the second year after sowing. Many growers find it less trouble to lift roots, and if the variety is reliable the supply from older roots will be greater. I find there is a great waste of material if roots are lifted where large supplies are needed, as much better results are secured by growing a quarter for the forcing house either by division of roots in the early

spring or from seed, as after the forcing the roots are of little value. Rhubarb can be forced under stages or any place where there are enough warmth and freedom from excessive moisture, as, though it delights in warmth and moisture at the roots, it does not like steam or vapour. A certain amount of air is necessary if colour and flavour are studied. For regular supplies from December to March roots should be introduced every three weeks according to the demand.

SALADS FORCED.—Under this heading will come such useful roots as Chicory and Endive. From now to March Endive will be of great value if batches can be placed in warmth every fortnight and blanched for salad. Chicory for forcing will now be in the open ground and may be lifted, the old top growths twisted or cut nearly close to the crown and the roots placed in sand in a cool shed, or, what is better, laid in soil in the open, so that in severe weather litter may be placed over them. Left in their growing quarters the roots do not force freely, but they soon start when placed in heat. If cut before the head opens it is delicious as a vegetable, and when developed an excellent salad. Mustard and Cress will need to be sown every ten days where salads are needed daily. From this date I find I get the best produce from boxes placed over warm pipes or close to the glass on shelves in a forcing house, the seed being sown on the surface and covered with brown paper till germinated. Avoid excessive moisture, as the tender plants soon mildew or decay. Fully grown Lettuce may be placed in warmth for blanching, but very little moisture will be needed. Dandelion will be a welcome addition to the salad bowl if blanched as advised for Chicory. S. M.

FRUIT HOUSES.

PINES.—**FRUITING PLANTS.**—The Smooth Cayenne and Charlotte Rothschild varieties are now the best kinds upon which to rely for well-finished fruits. Later on these, in conjunction with Black Jamaica and Lord Carrington, will afford a good choice. For midwinter I have always found the two last-named the most reliable, owing to my Pine pits being only accessible from the outside. This to some may seem but a small matter, but it is in practice all-important, and when it is not possible to have houses or pits with passage-ways inside of them it is best to rely upon kinds which will put up with a little rough-and-ready treatment both as regards watering and temperatures. With every convenience at hand in the way of suitable structures for Pine-apple culture, there never need be any fear but that a good return can be obtained, even in these days of cheap Pines from the Azores, which at the best are oftentimes sour, although all that one could wish in appearance. Small houses or pits—or at the most medium-sized ones—are much better for Pines at all seasons of the year, not that they cannot be cultivated in larger ones, but from the fact that more will at times ripen than are immediately required in the latter instances. Thus four or six small or medium-sized divisions are much to be preferred to half the number of larger ones, whilst at the same time greater economy could be exercised in the management. Pines now ripening should have the temperature well maintained (see last calendar notes, October 8, p. 285). An average of from 2° to 5° less will be better than firing too hard, whilst if it prove soon to be frosty it will be better to cover the glass at night, by which 5° difference will be obtained if it be windy at the same time. The watering of all ripening Pines should cease as soon as the slightest tinge of colour is evident, otherwise black cores may result. Those even which are now in their later stages of swelling must be very carefully attended to in this respect, otherwise they will not finish so well as is desirable. See that the bottom-heat is well sustained for these, also for any later batches, of which there may be occasional fruits in a semi-advanced stage.

SPRING-FRUITING PLANTS.—These should now be kept in almost normal condition. By this,

60° is meant as a night temperature, with a rise during the day of 7° or 10°, as the case may be. Keep this stock moderately dry at the roots, avoiding both extremes of moisture. When watering has to be done, let the water be chilled, say 75° or thereabouts. Should the early morning temperature be as low as 55° no harm will come to the plants. If kept quiet now they will respond all the more readily when the time comes to start them. Keep a close watch upon any stock in quite small pots. These will dry up rather quickly, being invariably near to the pipes in the front row. If these get too dry now they will frequently throw up small, puny fruits instead of starting into fresh growth in the spring.

BANANAS.—Except in the case of plants showing, developing, or ripening their fruits, the stock of these should now receive moderate rest. Do not, save when any plants are much pot-bound, now attempt to forward such by fresh potting. It will be better to defer this work until the change of days, when, even if it be impossible at once to increase the temperatures, there is the satisfaction of knowing that every week is more favourable to vegetation. My plants are all in pots, which in some cases look small in proportion to their occupants. I do not advise intending or present cultivators of the Banana to depend altogether upon the planting-out system. In fact, so far as my own experience goes, I prefer goodly sized tubs. The gross growth with noble foliage is all very well for appearance sake, but from the severely practical side, including a saving of labour, the preference so far must be given to the restricted plants. With the growth somewhat quiet now, it is a good time to thoroughly overhaul the plants for any insect pests, as scale or mealy bug, if this latter enemy is unfortunately present. Green fly will also give trouble upon the young leaves; it should be stopped at once when detected. Beginners in Banana cultivation will do well to keep exclusively to *Musa Cavendishi*, which it is hard to beat when a good stock is obtained. There seems to be a difference of growth in this variety, one being more compact than another. Plants now in fruiting stages should be maintained at a night temperature of at least 65°; nearer 70° will be better. During the daytime a rise of 15° will not be any too much when it is possible to attain it; at any rate, make good use of all available warmth to hasten the ripening. For the younger stock, 60° at night and 70° by day will be ample until the turn of days. Those who contemplate the growth of the Banana next season other than in the open border will do well to secure some tubs of about 2 feet in diameter, with a similar depth. These, if they have had oily substances in them, will be better prepared if burned out. Casks which have been used for wines do not need this precaution. Extra-sized flower-pots can also be turned to good account, but they should be strong and sound to commence with.

THE EDIBLE PASSION FLOWERS.—Notes have appeared from time to time of late in various papers upon these fruits. There may be some growers who might be able to give them a trial. Where this is the case I would recommend that *Passiflora edulis* and *P. quadrangularis* be chosen; both are good in their way. Personally I prefer the former, which when well ripened is greatly appreciated by some enthusiastic fruit growers. I hope to grow these varieties during the coming season in a lofty house now in preparation for Bananas. The planting-out system will be adopted in moderate-sized brick pits. With this object in view plants have been prepared of *P. edulis* (Roberts' variety being the choice). These will soon give a good account of themselves when warm weather again sets in, but anything tending towards an excessive growth will not be encouraged. Light training upon the roof seems to be a suitable position. The other variety, well known as the Granadilla, requires even more care not to foster a luxuriant growth, otherwise it would soon cover all available space. On the other hand, if held rather in check both as regards limitation of soil and not too much

moisture at the roots, a sturdy, hardy growth will ensue, which will result in greater freedom of flowering. With this reminder there may be some who would like to work the subject out to suit their own cases. There is at least the merit of change and novelty too in a dish of either variety for the dessert. A cultivated taste may be needful, but to bring this about is not at all a difficult matter.

VANILLA AROMATICA is another subject from amongst tropical fruits the culture of which is strongly advised. Here, again, is a plant that thrives well with the Bananas. It is grown in the Banana house at Syon Gardens in the most successful manner possible. Notes of the culture thereon have very recently appeared in *THE GARDEN*. Further remarks upon this detail would now be superfluous, as Mr. Wythes in his method of culture is reliable to follow. If for no other purpose than for the aromatic fragrance of the pods as they hang upon the plants it is well worth growing, but there is in addition the point of utility. It cannot be urged that a great amount of room is taken up in the cultivation of the Vanilla. With a sunny spot the back wall may be utilised, or else the warmest places in the front or at the western ends of houses where no shade is permanent. HORTUS.

KITCHEN GARDEN.

THE ROOT CROP.

In many parts of this county, at least, both in gardens and on farms, the various roots which prove so acceptable during the winter months appear likely to become scarce long before spring; indeed, on some farms the autumn sowing of what is termed white Turnips has proved so unsatisfactory, that what did appear has been grazed off by sheep, and the land either planted or prepared for another crop. The absence of rain for so many weeks prevented the seed germinating freely, and what plants did appear fell a prey to vermin, the growth in consequence being anything but clean and healthy. To a great extent the same remarks apply to garden crops. A limited store of winter roots, Carrots and Turnips particularly, often promises a harassing time for the gardener, as, though they may not be highly appreciated in the ordinary way in all dining-rooms, cooks, apart from the flavour they may extract from them, require an unlimited supply of fine specimens for cutting out small designs for fancy dishes, the greater part of each root being wasted. In most establishments, however, a variety of roots, provided they are of good quality, are not despised during the winter, as they afford a change when there is little other apart from forced vegetables to select from, and it is not uncommon for their appreciation for them to extend, or seemingly so, as the supply falls low. Moreover, what proves more useful than a good breadth of Turnips for supplying an abundance of their wholesome tops during the spring months, when perhaps a severe winter has cut off all the Brassicas, and it is then as well as during the coming winter that I fear their scarcity will be realised. In some gardens there may still be a number of Turnips left from an early sowing which, owing to the dry season, have become useless for cooking, but even these during a season like the present can be turned to good account—at least I am treating them here for this purpose with, I trust, a good chance of success. A portion of a crop of Veitch's Red Globe sown at the end

of June still occupies the ground. Growth of course has been slow all the summer, resulting in the roots being small, but they are perfectly sound and hard and should stand through the winter, furnishing a useful gathering of tops in due course. With a view to securing this desirable end it is necessary to lift them, as they are now spread over a large area, and bury them on a north border. I do not mean in the usual way in clamps, but the ground is dug over and the roots laid evenly into each trench as the work of digging proceeds. A large quantity of roots can not only be placed in a small plot of ground, allowing the site they occupied previously to be dressed with manure and dug up at once, but by burying them about 3 inches beneath the surface they are protected from frost, and few of them will decay during the winter. This is an old-fashioned method of keeping roots still practised in some gardens and worthy of consideration by all who wish to keep a good store. Such roots will be found quite good enough for flavouring soups, reserving a portion for supplying tops next March. This will be found to save the autumn-sown crops, which are either thin or backward, and so all will be done that is possible to stave off the much-dreaded famine.

With Carrots most vegetable growers have experienced the wisdom of not trusting to one general sowing to keep up the winter supply. Seasons and soil vary so much that this crop can seldom be depended upon from one main sowing, say in April. The roots may become stunted through the want of rain, or they are liable at the end of summer after a few showers to make a second growth before it is deemed advisable to lift them. If the roots do not actually crack, their quality is impaired, as they lose their bright deep colour and green rings form in the centres. This will be the case with many crops this season, I fear, judging by the quantity of rain which has fallen recently; indeed, the tops look more like growing now than they have done all the season. I find a sowing made at the end of July generally furnishes the best roots, medium in size and of good quality. At the present time this late sowing is decidedly better in every way than that sown early in April, proving that Carrots can be sown too early and have too long a season. When sufficient frost appears to cut down the tops, a dry day will be selected to cover a portion of the bed with long litter, as the quality of the roots is never better than when used direct from the ground. A reserve store in the root house, of course, is necessary to supply what is required during inclement weather. The past season has been equally trying to Beet. Medium-sized roots are always preferable, but not when their dwarfness is the result of dry soil and stunted growth, as, unless naturally tender in the grain, the extra boiling necessary to make it so results in the loss of colour, almost, if not quite, as objectionable. Extra care, therefore, will be necessary in storing this crop. A damp, cool place with plenty of sand or fine mould placed about the roots, covering the heaps or bins over afterwards with a good thickness of straw or mats, will help to keep them in good condition. A portion of the crop at least might be left in the ground, covering the crowns with ashes, or every other row might be lifted, and what remains be moulded up like Potatoes, scattering Bracken along the ridge should severe weather threaten. Parsnips have not suffered to the same extent as other roots during the prolonged drought, but in my case I account for this through sowing on a piece of trenched ground, which allowed the roots to strike downwards freely where there was more mois-

ture. The weight and quality secured more than repay the cost of the extra work. Although perhaps the Parsnip is considered the coarsest vegetable, it will undoubtedly prove very acceptable this winter, as necessity often creates appreciation or reduces aversion.

Goodwood, Sussex. RICHARD PARKER.

Parsley as an edging.—In the garden under my charge several of the walks are edged with rough stones. Some few years ago I resolved to sow Parsley close to them, allowing it to cover them. Some may say Parsley is a hiding-place for slugs, &c., but this is of no consideration, seeing I sow it every spring, and by the time it grows too large most crops are out of the way. It covers these stones and hangs on to the paths. Another recommendation to it is that by so doing a good bit of space is saved, and this to me is of considerable importance.—DORSET.

Late Beans.—Hereabouts where frost visitations have been only slight—so slight, in fact, that Dahlia and runner Beans are still growing and flowering—late gatherings of Beans have been, though not oft-repeated, very general. So late as the 1st of November quite a good gathering was reported from a cottage garden, and in my own case Beans are flowering and producing pods sufficient to get an occasional dish. I cannot remember another season when such a desirable vegetable was obtainable from the open so late, and the shortness of supply in the garden makes Beans more than usually welcome. The rainfall coming somewhat abundantly on a dry soil set up a late growth.—W. S., *Wills*.

Potato Snowball.—I have read with interest the notes of late in THE GARDEN on Potatoes, but so far I have not noticed any reference to the above variety. I had Snowball sent me for trial, and in spite of the soil being dust-dry for many weeks, this variety bore a fine crop. The tubers are of a nice size and there were scarcely any small ones. The quality, too, was very good. With me Snowball in quality was not unlike Schoolmaster, one of the best Potatoes in this respect, but the crop is much heavier. Snowball may be termed a midseason variety, though from appearance I should say it will keep well. The flesh is white, the skin rough, with few eyes, and the haulm strong, but not tall. No tuber lifted showed any disease.—G. W.

Celery Standard-bearer.—For some years the above variety has taken a high position among the coloured kinds, mostly on account of its splendid quality. It is difficult to add anything in its favour, as most growers well know its merits. My object is to note how well it succeeds in poor soils with only ordinary culture. Many gardeners have none too much manure at their command, and such will find Standard-bearer one of the best. It is not a gross grower and appears to do well in most soils. Standard-bearer was the result of crossing Major Clarke's Solid Red with a white Celery. Few Celeries keep better. I have had this sound well into May. It makes a small quantity of foliage for the size of stalk, few varieties being so solid. I grow it largely for midwinter and late supplies.—S. H. B.

Lettuces in dry weather.—I was pleased to see "E. M." speaking of Hicks' Hardy Cos Lettuce in such favourable terms, and can vouch for the accuracy of the statement that this variety is of hardy constitution and suited for winter work. Mr. Webb, gardener at Kelham Hall, Newark, invariably grows it for early spring cutting. Often have I seen a splendid lot of it on an early sheltered border, the plants not merely in a single row immediately under the shelter of the wall, as we frequently see the old Brown Cos planted, but extending the whole length and width of the border. Here they passed in safety all but the sharpest winters, and proved a boon in spring, the quality surpassing that of the old Bath Cos. Mr. Wythes on the same page refers to the difficulty gardeners have this summer experienced in providing good

Lettuces for the salad, and prefers adopting the non-transplanting system. Much greater success, however, might be obtained if in hot weather seed were sown on well-moistened ground on a north border and the seedlings eventually carefully planted into trenches of medium depth well enriched with manure, and thoroughly soaked a day or two previous to planting, lifting each plant with as much soil attached as possible, and shading with evergreen branches for ten days. In such a position the roots reap the benefit of all the water that may be given them, while the sides of the trench afford a certain amount of shade till the plants are of good size. Another capital dry weather variety is Alexandra Cos. I grew it for years, and was seldom without plenty in the worst seasons, and that even in a light, shallow soil. Mr. Wythes speaks well of Continuity as a drought-resister, and he is fully justified in doing so. I had a trial packet of seed sent me at the time it was distributed, and I have ever since recommended it. It is more bronzy outwardly than any variety I know, but the hearts are of good colour and quality, not the least thing in its favour being its non-liability to run quickly to seed. A common error is planting out too many Lettuces at one time and not sowing often enough.—J. C.

THE EARLY CABBAGE CROP.

THE ground being now in fine condition, it will be well to make a large planting of Cabbages, as there will be little danger of failure. Unless I am much mistaken, the demand for young Cabbage in the spring will be greater than usual. There is a great scarcity of Cabbage plants, in many cases large growers have a difficulty in obtaining plants, those who are fortunate enough to have them to dispose of realising high prices. Owing to the heat and drought, fully three-parts of my plants failed, though they received ample attention. The plants went blind, and this is a common failing in most parts of the country. I notice the plants saved from the earlier sowing do not look happy. They are infested with fly, and so far have made but little progress. I am now dusting over freely with soot, and the rain will help them to make a fresh start. I am much better pleased with a later sown lot of plants. Noting the failure of the earlier lot, I sowed more than usual, and these, though small, will be the best material. Now is the time to make good any losses, as, though we are close on November, the soil is in a workable state, and the plants will make roots as long as we get mild weather. I always plant 15 inches apart each way. Many will think this much too close, but, needing a great quantity of green vegetables early in the spring, I do not hesitate to take a whole row at a cutting, thus leaving ample room between the trees. If this is objected to, it is an easy matter to cut every other plant in the row. Many would prefer this. I draw the whole row, this allowing the hoe to be used freely and fertilisers also to hasten the crop if the ground is at all poor. Where there is a large demand, one must have a succession. In the desire to get Cabbage as early as possible we are at times apt to forget the succession crop, and though such kinds as Ellam's are invaluable, these early varieties of Cabbage do not remain solid long. Many people sow in frames early in the year for succession, but I do not advise it. Such plants are not ready much before midsummer. They need shelter at the start, and in the end cause a good deal of work. My note refers to the supply from early April to the end of June or up to the time Peas and other choice vegetables are fairly plentiful. A good quarter of plants for the period named will be found most useful. I find such varieties as the Early Offenham useful. This is a very shapely, good quality Cabbage, much grown in the midlands for the Birmingham markets. There are other good kinds, such as Mainerop, April, and Flower of Spring. For a private garden I do not advise large kinds, which need more space and are longer in coming into use. I would also note

the value of pricking out surplus plants at this date. They winter better, as if left in the seed beds they get long and weak. If pricked out, roots form close to the leaves, and they come in useful for filling up blank places. These make a good succession to the early spring supply if planted out in rich soil at the end of February or early in March. S. M.

FORCING FRENCH BEANS.

THE earliest made sowings of French Beans under glass are tolerably easy to manage, and good gatherings may, as a rule, be relied upon. It, however, requires a good deal of tact to induce those batches which are to produce Beans during the short, dull days of December and January to grow and crop freely. Large pots and rich compost are now things of the past, as gardeners have found that, unless the roots are in a warm medium and one which dries fairly often, the plants make poor, unproductive growth and are not worth the trouble entailed. In gardens that have suffered much from the prolonged drought, forced Beans will during the coming winter be specially valuable, as choice outside vegetables will be none too plentiful. Where French Beans are in great demand, it would pay to erect a house especially for their culture, as during the summer months it could always be put to a profitable use for the growth of various plants, or even Tomatoes. Such a structure would require to be light and supplied with plenty of hot-water piping, so that the necessary temperature could be maintained without unduly heating the pipes. Without this precaution the atmosphere would in severe weather become too arid and foliage disfigurement from red spider inevitable. A stage or tier of shelves erected within a short distance of the roof-glass would be best, also ample ventilation. Many gardeners who do not adopt the planting-out system use 6-inch pots successfully, but I think boxes similar to those usually employed for cuttings, but a little deeper, are best. Mr. Taylor, when at Longleat, used boxes and grew French Beans as well as most people. His contention was that the roots had a chance of permeating such a limited depth of soil and feeding could be resorted to. Use a poor rather than a rich soil, excluding animal manure altogether, and trust to feeding later on from the surface. Sow thinly, keep the soil on the dry side until the plants are up, and always use new seed. When in boxes a few twigs inserted in the soil will prevent the haulm falling about. J. CRAWFORD.

Onions.—In judging Onions as now presented for show in competition, too much stress is laid on mere size or weight and not enough on form, solidity, brightness and clearness of skin. In the rules of judging of the Royal Horticultural Society, although out of a maximum of seven points size is awarded two, so also is condition, as that is of special importance, judges should in determining the best of several collections pay the greatest deference to solidity and finish, as these are indications of good keeping. In a recent Onion competition I saw huge bulbs were awarded prizes solely for size, yet had rough, discoloured coats and with some flesh already softening, because fed up to be a mass of watery pulp rather than of solid, firm flesh. It is very rare that big bulbs have the most perfect finish. The skins should be silky, almost bright, clean, and setting tightly on the bulbs, and not loose or broken. The bulbs should also be very firm about the necks and have them small and almost dry, indicating that thorough ripening has resulted. Large Onions have a high value as food, boiled, baked or otherwise cooked, but the best for this purpose are those with fairly solid flesh and mild in flavour. They have an equally important value in some cases, perhaps greater, in being the agents for giving a fine seed stock. But to be useful for this purpose, they must be good keepers that can be kept rested until February, when they may be planted. How few of the huge watery bulbs that have won prizes are sound by Christmas, much

less two months later? Surely some consideration should be paid to that desideratum. We refuse to grant prizes to other vegetables, whether Potatoes, Tomatoes, Cucumbers or tap-rooted kinds, simply because large. A certain evidence of table quality is invariably desired, and that rule should prevail in the case of Onions, for with them the biggest are far from being the best. —A. D.

FLOWER GARDEN.

THE KEW BELLADONNA LILY.

THIS is far superior to all other known varieties of the Belladonna Lily. It was supposed to be a hybrid, *Brunsvigia Josephinae* being the other parent, but no trace of the characters of the latter can be found in it beyond the large number of flowers in each umbel. Whatever its origin, it has proved a first-rate garden plant at Kew, where it is grown against the south wall

inflorescence of the type and of the Kew variety are shown side by side. Bulb fanciers generally who have seen this plant at Kew agree in calling it the handsomest of all outdoor bulbous plants. It has been distributed from Kew to a few gardens, so that no doubt it will soon be abundant. W. W.

Annual Centaureas.—I was much pleased, on opening my copy of *THE GARDEN* November 5, to find a coloured plate of the charming annual *Centaureas*, or, as they are popularly known, Sweet Sultans. They are so useful for cutting throughout the summer months that no garden should be without them. The plants, if thinly disposed so that they do not become drawn, make exceedingly pretty isolated beds on grass, and give great quantities of flowers if the precaution is taken to pick off the seed-heads as soon as the blooms fade. Planted in groups of from three to six plants they are also effective in mixed borders. I generally grow the white and yellow varieties,

Amaryllis Belladonna (Kew variety) and the type. From a photograph sent by Mr. W. Watson.

of the tropical Orchid house and also in an unheated frame. Every autumn it has produced its magnificent flower-heads, and it has increased rapidly by means of bulb-division. In the same border there are numerous plants of the type, and the difference between these and the Kew variety is most marked. The former has leaves an inch wide, a scape 18 inches high, and an umbel of from six to ten flowers, rarely the latter number. These open three or four together, and they have narrow, pointed segments coloured rose-pink, paler inside. The Kew variety has leaves 2 inches wide, a scape 3 feet long and 1½ inches in diameter at the base, and an umbel of twenty or more flowers (that here figured bore twenty-six) which are nearly all open together as in the Jersey Lily (*Nerine sarniensis*). They are larger and have broader, less pointed segments than the type, and their colour is bright rose-crimson, changing to almost pure crimson with age. In the photograph, which was taken by Mr. A. Griessen, an

and raise them about the beginning of April, planting out the seedlings afterwards as early in May as is consistent with safety. Being so sweetly scented, the flowers are highly prized by many in a cut state for drawing-room decoration.—A. W.

Tricyrtis pilosa.—It is only rarely the few species constituting this genus are seen in good condition, and the above species least of all even then, but this year the exceptional heat would have appeared to suit it to a remarkable degree. It is a genus remarkable rather for quaintness of character than for its flowers, and the above species especially so. Usually the plants flower too late in the year, and the blooms are either killed outright or so disfigured by frost and wet as to render them worthless. The above-named species, however, in a rather sheltered position in the rock garden at Kew has been quite a feature for a much longer time than usual during the present autumn. The long arching stems, fully 4 feet in length, are clothed with large heart-shaped leaves, the latter covered with a short, dense down, which is very soft, the same pilose

character occurring on the stems and branches. The curious and elegantly spotted flowers are produced in great numbers on much-forked branches, and these, arching over, form a very striking and unusual object in the garden quite late in autumn. The segments are whitish, yet copiously marbled with violet and purple spots. The stigma is likewise also similarly marked, and forms a very curious and interesting feature among liliaceous plants. It inhabits the Himalayas, and thrives best in rather moist peat and leaf soil.

Cactus Dahlias in November.—Rarely at a Chrysanthemum show in November has there been seen such a superb display of Dahlias, especially of Cactus varieties, as was made at Kingston on November 1. Seldom have these Dahlias attracted so much notice. Nearly all the flowers were in exceedingly fine form and the colours were beautiful. In this respect, apart altogether from the quaint build of the blooms, which to so many who saw them was so new and attractive, their rich colours far excelled those of the Chrysanthemum. So far as these latter flowers are concerned, something that is thus disparaging is due to the too common practice on the part of growers for exhibition of setting up fully 70 per cent. in their stands of white and yellow flowers, real colour being so much lacking. Singularly tame in this respect were the finest stands of Chrysanthemums compared with the beautiful Dahlias. Even the show flowers, so largely staged, also were wanting in brightness compared with the beautiful Cactus varieties. Very fine and in perfect form were Starfish, A. J. Deal, Mary Service, Cycle, Charles Woodbridge, Arachne, Fantasy, Alfred Vasey, Keynes' White, Ebony, Mrs. F. Fell, Harmony, and fully a dozen others. In this case the plants had been grown in a dry, airy position, and recent rains had given to them new life and vigour, allied to charming hues of colour. It is very evident that the more these Cactus Dahlias are seen and known, the wider will they be grown. We have, indeed, no outdoor flowers so singular in form, so rich in colour, and so attractive in a cut state as these are.—A. D.

NOTES FROM CLAREMONT.

AFTER a hurried visit, the conclusion I arrived at is that Claremont is one of those interesting historical places that should be preserved as much as possible in its present form. Having recently inspected modern gardens in all their glare, excessive trimness and general appearance of having been too much given over to the builder rather than a landscape gardener of the right stamp, it was a relief to spend a few hours with Mr. Burrell strolling among the beautiful and in some instances rare trees, and from one old-fashioned garden to another. Time was when Claremont was reckoned among the most noted gardens in the country, and never more so than when the exiled Bourbon princes were living there, but the glazed structures that were good of their kind in those days are in these times regarded as very old-fashioned indeed. They are there still, and in all probability never doing better service than now.

No attempt will be made to describe all or even a tithe of what there is to be seen of interest at Claremont, but mention ought to be made of a grand specimen tree of *Pterocarya caucasica* growing on a lawn between some of the walls abounding in all directions. This magnificent tree has a spread of branches measuring 100 feet, and is in every way ornamental. In another direction a fine specimen of *Salisburia adiantifolia* is to be seen, and equally noteworthy is a garden wall 60 yards long and 13 feet high covered by a single tree of *Wistaria sinensis*, while just outside of the kitchen garden is one of the finest hedgerows of naturally-grown Hollies to be seen anywhere. No stiff, gaudy bedding-out came under my notice, but everything of a hardy nature worthy of garden culture seems to find a place in the various large beds and borders in and

out of the kitchen gardens, not in mere dribblets, but in most cases in bold effective groups. In Surrey, as elsewhere, the rainfall during the summer and early autumn months was very light, but the well-tended flower borders showed but few signs of this.

Fruit is grown under glass on a fairly extensive scale, and the Grapes left hanging on the Vines were of the right description for the dining table. Large numbers of pot plants suitable for house, table and conservatory decoration, and for providing abundance of cut flowers abounded. Among the less common of these I noted a large batch of *Laxandra macrantha floribunda*, neat, bushy plants commencing to flower freely, and these only in 5-inch pots. *Asparagus deflexus*, from seed sown in the spring of 1897, was to be seen in large quantities interspersed among flowering plants. For relieving the heaviness, or rather nakedness, of a great ugly roof of a high greenhouse or conservatory, nothing could well surpass *Colea scandens* as seen at Claremont. Two plants are equal to festooning the roof in a most attractive manner, the long trails of handsome green leaves, large purple flowers and numerous egg-shaped seed-pods favourably impressing all who see them. In an adjoining tall house originally constructed for Palms there is an extraordinary tree of Noisette Rose *Réve d'Or*. It was planted sixteen years ago, and now covers a trellis surface equal to 900 square feet, reminding me of the magnificent specimen of Fortune's Yellow Rose to be seen in the conservatory at Berkeley Castle, Gloucestershire.

Having been a fruit and vegetable garden so many years, I should not have been surprised to find many of the fruit trees against the walls and in the open in a worn-out state, or showing signs of exhaustion, but nothing could be further from the actual state of affairs. The walls are, as a rule, 12 feet or more in height, and throughout are perfectly furnished with fruit trees. The Plum trees are in perfect health and are really inclined to be too vigorous, Mr. Burrell allowing some of the topmost young shoots to extend temporarily each season by way of an antidote to over-luxuriance. The trees bear well, and the fruit I saw was of exceptionally good quality, or such as would have won prizes at the Crystal Palace show. The Peach and Nectarine trees, again, are in a healthy, productive state, the fruit produced being of the best quality this season. Apples and Pears are in an equally satisfactory condition, the fruit of the former growing larger than is often seen under ordinary garden culture.

Having only a few hours previously left the Crystal Palace show, where so many gardeners were complaining of the scarcity of green vegetables and the lightness of crops generally, I expected to find something of the same character at Claremont, but Mr. Burrell is in the happy condition of having crops equal, or even superior, to what are usually met with elsewhere in the most favourable seasons. To good cultivation and a free-working or non-binding, non-cracking surface soil may be attributed this success. Borecole, Broccoli, and Brussels Sprouts were all to be seen in a luxuriant condition and free of caterpillar. Excellent Cabbage was being cut, and Mr. Burrell has every reason to speak favourably of Garden Drumhead as a good summer Cabbage. Bristol market growers have formed an equally good opinion of the merits of this variety, caterpillars not disfiguring the hearts as they are apt to do conical-shaped Cabbages. The Onion crop was exceptionally good, and nowhere else have I seen a better lot of "bulbs." The estimated weight grown per square rod was $1\frac{1}{2}$ cwt., or 10 tons to the acre. Giant Zittau and Brown Globe are the varieties grown at Claremont, and two more serviceable or profitable sorts could not well be named. The Potato crop was also a great success, and the envy of a market grower, who grows Potatoes on a large scale, accompanying me. Of Windsor Castle, perhaps the most popular variety in cultivation, the crops lifted were equal to 12 tons per acre—nearly all

"ware" or large, saleable tubers, too. Mr. Burrell also speaks very highly of Ninety-fold. This kidney he finds earlier than Windsor Castle, the crops equally heavy and the quality unsurpassed. W. J. GULLEN.

ORCHARD AND FRUIT GARDEN.

RENOVATING FRUIT BORDERS.

WHEN it is considered how little trouble is involved in giving assistance to partly worn-out borders, and how greatly the trees appreciate this attention, it is singular that this detail of culture is so long postponed. Many growers, for some reason or other, seem very much averse to breaking into a fruit border whether it is in a Peach house or vinery. A great deal, of course, may be done by judicious surface feeding, but there comes a time when the best made borders require renewing, and whether this is done wholly or in part largely depends upon circumstances. In my own case a scarcity of good loam prevents the attention necessary being given to trees outside, and doubtless there are many others similarly placed. Most of the inside fruit borders here have been made within the last few years, so that the trees have still a good deal of the initial vigour in them. They have, however, carried big crops, so I am renovating the greater part of the borders in a 30 feet by 16 feet house, to prevent any loss of vigour or exhaustion. A Vine, for instance, weakened by carrying a large crop from a rather poor border will take several seasons to get over the shock. Peach or Nectarine trees starved into making poor growths one season, start weakly the next, and instead of the basal shoots coming away with vigour, these make a few leaves only, and one has to make the best of foreright shoots. A few seasons like this and the most of the growth will be on the outside of the tree, all the centre being bare; consequently only half the space covered by the tree is profitable. With properly fed Vines or Peach trees there is no difficulty in getting the growths where they are wanted.

An excess of vigour is, of course, just as much to be guarded against as the reverse conditions, and this will be kept in mind when making new or renovating old borders. The present is the best season to do such work, and it must be done as thoroughly and with as much despatch as the circumstances of the case will allow. My compost has been gradually accumulating and is now all ready for use. It consists of all the loam that could be spared, this being helped out by edgings of turf, potting bench refuse, and a large proportion of burnt garden rubbish prepared as recently described by several correspondents. Where lime is deficient in the natural soil, this should be added in some form or other. Wind-slaked chalk lime is an excellent addition where plenty of rough material already exists or is added in the form of broken brick, charcoal, or even flints if nothing else can be had. But the fining tendency of pure lime must not be lost sight of, and for this reason I always like a good percentage of old lime rubble in preference if it is to be had. There is not the same amount of strength in it, of course; pure lime unlocks other chemical constituents in the soil to its benefit which the lime rubble does not perhaps so quickly, but by acting mechanically it prevents stagnation and ensures a supply of air to the roots. All compost should if possible be ready a month before it is required for use, and is better for being turned twice or thrice to well incorporate

all the ingredients. All being in readiness and in the dry, no delay will be caused when the work is about.

Taking Vines first, if these seem to be in fair condition at the roots and only require a little fresh soil, this may be given by beginning at the back of the border furthest from the stems and taking the soil out. Possibly there will be no roots. In this case follow the border back, making a kind of trench, and throwing the soil right out until roots are found. An inspection of these will show what is wanted. Often all that is necessary is to work out with a four-tined fork all the old soil from among them, going back about a yard or so. Then relay in the new compost and replace all soil taken out with new. If this is done a little at a time and carefully, not the least harm can possibly accrue to the Vine roots, and the foliage being still on the Vines a good soaking of water may be given, and they soon regain a hold. They should be kept fairly high up in the border, the upper tiers being covered with a few inches only of soil. Ram the new material very firmly as it is brought in, avoiding, of course, injury to the roots in doing so. With regard to Peach and Nectarine trees much the same plan is followed either inside or out. Very often indoor trees have larger, more vigorous roots than are necessary, this being especially the case with young trees that have only been lightly cropped. Then the autumn treatment takes the form of simply root-pruning, very little new soil being needed in such cases. Search out the long, thong-like roots and cut them off with a keen knife, relaying all the smaller more fibrous portions with care. But when taking the soil out at a considerable distance from the tree, I take little account of the roots, for if the ends are cut they soon start again and ramify in the new compost to the benefit of the trees. Here, again, firm soil is an absolute necessity if the right kind of roots and wood is to be produced. All this, though it seems a big job, gives very little trouble in reality; it may be carried out in wet weather when men can be easily spared from outside, and is of the greatest benefit to weak trees.

H.

Apple Tyler's Kernel.—At the present time I have before me a perfect specimen of Tyler's Kernel Apple, one out of many produced by a single pyramid tree I planted about four years ago, and the good character given me of this variety by a friend has been amply borne out by experience. Although classed as a cooking Apple, it is not to be despised for dessert, medium-sized, highly-coloured fruit forming a perfect dish any time from October to January. The tree grows moderately strong and bears freely almost from the commencement. The fruit is medium-sized to large, conical in shape, and where exposed to the light and air colours grandly. Curiously enough, not many trees of it appear to have been planted by either market or private growers, and the sooner this mistake is rectified the better. At the Crystal Palace show Messrs. Veitch and Sons exhibited a large basket of fine fruit of this Apple.—W. I.

Packing Peaches.—I have seen an illustration of the first prize box of Peaches at the late Palace show. These were sent by train, as if being sent to market, the Peaches being embedded in wood-wool. My favourite way of packing Peaches is first of all to line a box, just deep enough to hold a single layer of fruit, with coarse cotton-wool, which can be purchased at a nominal price in long rolls, then to encircle each Peach with narrow strips of the wool, taking care to place the glazed side next the fruit, packing them closely and firmly together, and finally laying on the top a sheet of wool. When the lid is on, damage from bruising is next to impossible, as

the fruit cannot stir. When the lid and top sheet of wool are removed, the top of each fruit is visible and the fruit has a neat and attractive appearance. I first saw this plan of packing adopted by Mr. Edmunds, of Bestwood, who often exhibited Peaches, and after long rail journeys and frequent changes his fruit always turned out well.—N.

Plum Coe's Golden Drop.—At page 306, "W. S.," in referring to this fine dessert Plum, notes that occasionally fruits are kept well into November. This is correct, and I remember seeing a magnificent dish shown from Rendlesham Hall, at Ipswich, in the second week in November. On speaking to the exhibitor about them, he informed me that the fruits had been finished off on a shelf in a cool, dry vinery, and also, I think, wrapped separately in paper. I think, however, that in the majority of instances these late fruits

when ripe to yellow and having a large number of russet spots. The flavour is distinctly good, and from healthy trees there is none of the hard, gritty core so often complained of with this kind. It should hang until it parts readily from the tree.—SUFFOLK.

FRUIT TREES ON ARCHES.

The photograph of fruit trees on arches which I sent you was taken by my son, Mr. Scott Wilson, at Oakwood, Wisley. Many years ago I saw at Wandsworth Common arches of this sort which had a good effect. I copied these in the garden here, putting arches over the walk which divides the vegetable from the flower garden, and as this was successful and made a good boundary, I adopted the plan at Wisley,

Fruit trees over a pathway in Mr. G. F. Wilson's garden at Wisley. From a photograph by Mr. Scott Wilson.

are from standard trees. These are always somewhat late in ripening, especially in ordinary seasons, and if left on the trees too long are apt to split should the weather be showery. If gathered in the nick of time and treated as above described useful late dishes may be had. Those referred to were fine in colour and quite plump. My experience with Golden Drop is that the locality must be a favoured one for standard trees to bear regularly even half a crop.—C.

Pear Beurre Diel.—This is one of the hardiest of the Beurré race and an excellent variety for cold or exposed positions. It will also thrive in poor and heavy soil where many first-class Pears are a failure. An old espalier tree here fruits every season, while young pyramid trees on the Quince planted two years ago have given some useful fruit this season. The fruit is large, with a long stem, the skin green, changing

and as the trees were already in their places, trained one side of them over the arches. The first arch has the Dartmouth Crab trained over it; this is beautiful both in flower and fruit. The other trees are principally Pears and Plums. The end arch has on it Turner's Crimson Rambler and Paul's Carmine Pillar Roses, as it joins on to part of the flower garden.

GEORGE F. WILSON.

Heatherbank, Weybridge Heath.

Compost for Muscat Grapes.—At one time it was universally thought that a strong yellow loam produced the finest Muscat Grapes. Lately, however, some writers have maintained that a light soil and a liberal quantity of sand are what this somewhat capricious Grape needs. The fine

bunches recently exhibited at the Crystal Palace by Mr. Allan, gardener to Lord Hillingdon, were cut from Vines growing in a strong clayey loam, kept open by the addition of plenty of rubble. At Hillingdon shanking gives little trouble, the berries keep plump till late in the season, and the Vines last many years. Although the bunches under notice were cut from young Vines, there are old Vines growing in the same kind of loam which produce first-rate crops of long-keeping Muscats. Comparatively few really fine Muscats are grown in Norfolk, the reason being, according to the opinion of a practical old Grape grower, the too light nature of the soil procurable for making the borders. The Hillingdon Muscats were grown in a span-roofed house, and the majority of the bunches now hanging on the Vines are almost as good as those exhibited.—N.

Peach Princess of Wales.—I am obliged to "M. T." for his hint respecting pot trees of this Peach, for I would really like to grow this fine variety well. It is rather curious and, perhaps, worthy of note that some few of the later fruits on my tree were excellent, and this appears in a way to bear out what "M. T." says about the warmth later, for the weather was much warmer here in early October than usual. I shall certainly try one or two pot trees.—H.

—Doubtless the flavour of Peaches varies in different soils and situations. I do not think that the majority of gardeners will agree with "H." (p. 255) that Princess of Wales is a flavourless variety. In a sheltered old garden near Cromer, Princess of Wales from an open wall was of excellent flavour, and at Blickling, where good flavoured Peaches are a speciality, this variety is appreciated, more so than Sea Eagle, the tree here growing in a late house and occupying the front trellis, the fruit ripening early in September. At Kelham Hall, Newark, Mr. Webb grew Princess of Wales in an east aspect Peach-house in company with Walburton Admirable, and he used to think the Princess the better flavoured of the two. Had it not been at least of average flavour, generally speaking, I do not think it would have remained popular so long, as flavourless varieties, though fine in appearance, soon fall into disrepute, as, for instance, Lord Palmerston. It would, however, be interesting if other growers would give their opinion of this variety.—NORWICH.

TREE TOMATO.

(*CYPHOMANDRA BETACEA*)

A LARGE plant of this, bearing about 200 ripe fruits, is now a conspicuous feature in the Mexican house at Kew. The plant is a seedling, about two years old, with a clear stem 5 feet high and a large spreading head, having numerous large bright green heart-shaped leaves, each from 6 inches to a foot in length, in the axils of which the short pendent racemes of flesh-coloured flowers are produced in spring and are succeeded in autumn by clusters of from three to six fruits, which are egg-shaped, 2 inches to 2½ inches long, smooth, and when ripe coloured bright orange-yellow, with a few streaks of a darker colour. A cross section of the fruit shows a skin or pericarp nearly a quarter of an inch thick, fleshy and orange coloured, enclosing a juicy pulp and seeds not unlike those of a Gooseberry or the fruit of *Passiflora edulis*. Eaten raw the fruit suggests a mixture of Passion Flower and Tomato, and is both pleasant and refreshing. On the mainland of Central America it is known as the Tomato de la Paz, in Jamaica as the Tree Tomato, and sometimes, on account of its supposed beneficial action on the liver, as Vegetable Mercury. Seeds of it were distributed from Kew some years ago, and it is now popular in some of our tropical colonies and in India. In Ceylon, at Hakgala, 6000 feet above sea-level, where the climate is temperate, it grows to a height of about 10 feet, and the fruits are used in various ways. They make excellent tarts, are very good stewed, and are much relished by most people when quite ripe and eaten raw like Gooseberries. The plant is very robust and easy to grow in Ceylon, and I believe it will thrive

and be very profitable from an elevation of 2000 feet to 6000 feet. Under favourable conditions the plant remains in bearing for many (ten or more) years. The fruit keeps well after being gathered, has a tough skin and travels well, and it is attractive in form and colour.

Being so easily grown in an intermediate house, or even a sunny greenhouse, in this country, and bearing an abundant crop of fruit in about two years from planting, this is surely a plant to be brought into general cultivation. Even if the fruits were not edible, the plant bearing them is good to look at. The plant is as easily managed as the Tomato, but it requires more space. It is a native of the Andean regions of Tropical America, and appears to have been first introduced under the name of *Solanum betaceum*.

W. W.

NOTES AND QUESTIONS.—FRUIT.

Apple American Mother.—I was not aware until lately that this Apple would succeed as a pyramid even in northern localities. I have only tried it in espalier form, but have not succeeded in inducing it to fruit freely. Presuming, however, the version as to its hardiness and free-fruited character being correct, no garden should be without at least one tree of this handsome conical, richly-flavoured Apple.—C. NORWICH.

Apple Lord Derby.—Intending planters having a strong soil may plant Lord Derby with every confidence. It would be difficult to name a better all-round cooking Apple or a more constant bearer. When at its best about Christmas it is a very good dessert Apple. In a strong, retentive loam at Kelham Hall Lord Derby grows and fruits to perfection, and is regarded as one of the best market Apples of its season.—C.

PUBLIC GARDENS.

CHRYSANTHEMUMS IN THE PARKS.

VICTORIA PARK.

THE atmospheric conditions which usually prevail here militate against the successful cultivation of the Chrysanthemum. Some 2000 plants comprise the collection, and as this embraces all types of the flower, the display is thoroughly representative. The arrangement of the plants, in which undulating groups run through the whole length of the show-house on either side, and in which the disposition of the colours was well conceived, was pleasing. The breaking up of the groups with masses of some of the prettiest of the decorative sorts, such as Ryecroft Glory and other equally valuable varieties, also lent considerable effect to the display. One specially noticeable feature was the brightness of the respective colours. Late buds of M. C. Molin were developing blooms of the brightest bronze-crimson. An old sort, Gloire du Rocher, showed blossoms of high quality. President Borel, rarely seen in collections now-a-days, was of large size, refined, and of a bright carmine-rose colour. Mme. Edouard Rey, with large massive incurved Japanese blooms; Hamlet, a popular flower of a few years since, and quite up to the original standard; William Tricker, noticeable on account of colour; Col. W. B. Smith, Admiral Avellan, and M. Pan-koucke each were represented by fine blooms, and proved that many of the older sorts when properly grown are quite equal to a large number of the newer sorts. Of the newer Japanese varieties, those calling for special mention are N.C.S. Jubilee, represented by blooms of massive build, and of a pleasing silvery lavender tint; Australia, particularly good, and striking in appearance; Mrs. Hume Long, coming as fine from late buds as one could wish, with broad petals of great length and of a rich rose-pink colour, so different from an early bud selection, and Marjory Kinder, a rich yellow of splendid substance. Lady Byron as seen here proves that the variety, although a beautiful white, does well even under impure atmospheric conditions. Nor must we

omit to mention Lady Ridgway, a massive salmon-buff incurved Japanese flower, and the green-tinted Mme. Ed. Roger. Decorative Japanese varieties were represented by Source d'Or, the old gold flowers of which were very welcome, Mr. Chas. E. Shea, the lovely soft yellow sport from Mlle. Lacroix, and others. Very charming were the Anemones, most conspicuous being freely-grown plants of Descartes, and as seen in flowers from late buds, the crimson-red colour was most effective. Gluck, too, is still valued for its consistent behaviour, although the blossoms are not by any means large. Fleur de Marie, white, and Mrs. Judge Benedict, opening pale blush, passing with age to white, with a lemon-coloured disc, were often in evidence with typical blooms. M. Charles Lebocqz, a fine citron-yellow-tinted carmine, and in conjunction with a new pure white named Mrs. Caterer, very freely flowered, contributed much to the display. Pompons, such as Mlle. Elise Jordan were grouped in clumps, and these, together with some of the best singles, including Miss Mary Anderson, as a fringe to the groups on either side gave a pretty finish. Among the incurved sorts Prince of Wales, very rarely indeed seen at exhibitions now, was very good; Prince Alfred, also one of the older types of the flower, and the members of the Rundle family were charming. These of more recent introduction were seen in Baron Hirsch, the bronzy crimson colouring being quite distinct from that of all others; Chas. E. Curtis, very even; Yvonne Desblanc and Mons. Desblanc, also welcome on account of their neat and even form. Mention must be made of the value of some pretty little plants of the rich crimson reflexed Cullingfordi.

FINSBURY PARK.

Chrysanthemums are usually well grown here, and this year's display was one of the best we have seen. The show-house, specially constructed for these annual displays, is an ideal place for the purpose. A long series of imposing groups running continuously from one end of the structure to the other, with a semi-serpentine path along the front, gives a most picturesque effect to the arrangement, and there is much in the method to commend it. The somewhat slender-looking iron pillars supporting the roof have grouped around them bush plants of popular Japanese sorts, well-grown specimens of Margot and the pure white Lady Selborne relieving the greenhouse of much of the undesirable effects of its inartistic supports. Along the back of the group, and forming an admirable background, were other freely-flowered specimens, the old *Hile de Plaisir* with its pretty deep crimson blossoms being most effective. It is a pity this system of culture is not more often recognised, as a few plants judiciously placed assist so much to relieve the stiffness which generally characterises the grouping together of the larger flowers.

At Finsbury Park the Chrysanthemum is grown in large numbers, 4000 plants of different types of the flower receiving attention. In addition to the ordinary show house a large conservatory has to be furnished, and this being filled with freely-flowered specimens in conjunction with the free use of fine-foliaged plants for a background and for associating with the flowers, a most elegant arrangement was seen.

Incurved varieties represented in good form this season are Baron Hirsch, still one of the easiest and most certain varieties to grow; Prince Alfred, with neat and even finish; Mrs. Heal, very like Princess of Wales; Mrs. R. C. Kingston, a splendid incurved flower of refined form and delicate colouring—pale lilac-pink, tinted white; Prince of Wales, the Egyptian, a coarse-looking blossom; Barbara, Chas. E. Curtis, grand flowers, clear yellow; Mrs. George Rundle and its sports. Japanese sorts are always well done at Finsbury Park, and this reputation is again borne out. Of the older varieties succeeding well this season are Louise, with its white and rose-tinted blooms; Mrs. E. G. Hill,

pale flesh-pink; Phœbus, still one of the best yellows; Mons. Chas. Molin, in fine form and colour, more particularly from a late bud selection; the dwarf crimson-flowered J. Shrimpton, an ideal plant for grouping; G. C. Schwabe, Golden Gate and Hairy Wonder, represented by flowers in all stages. Edouard Audiguier, the rich purple-amaranth, with silvery reverse, which caused such a sensation some years ago, was also striking in appearance. Edith Tabor may be counted as a yellow sort that has exceeded most growers' expectations this season; Mrs. J. Shrimpton, Viviani Morel and Chas. Davis, each calling for a word of praise. Newer Japanese were dotted here and there among the others and created considerable interest. Mrs. A. Cross, a large rich yellow; N.C.S. Jubilee, pale silvery lavender, of incurved Japanese form; G. J. Warren, the rich yellow sport from Mme. Carnot; Master H. Tucker, crimson, with gold reverse; and Mrs. H. Weeks, the refined and massive white incurved Japanese, doing much to provide the necessary novelty. Anemones as seen in Sir Walter Raleigh, Mrs. Judge Benedict, Marguerite Solleville, deep lilac, and other standard sorts were also good. Reflexed, pompons and singles each made a goodly show, and the representative character of the display must contribute in no mean degree to the lively interest in the Chrysanthemum in North London, judging by the immense number of visitors.

SOCIETIES AND EXHIBITIONS.

NATIONAL CHRYSANTHEMUM SOCIETY.

NOVEMBER 8, 9, AND 10.

THE annual show of this society, held on the above dates at the Royal Aquarium, Westminster, may be considered a success. With but very few exceptions, the prizes offered in the different classes were well contested, and many exceedingly close competitions have to be recorded. The Japanese blooms as a whole were well represented, though not so generally even as in most seasons. While there were many huge blooms also possessing good form and colour, there was a greater number which may be characterised as somewhat lacking in substance. Considering the drought and great heat of the past season, it is surprising that the incurved blooms were so freely shown and in such good form. There were many very rough and irregular flowers. Decorative exhibits were numerous and pretty. The trained plants were below the average, and better exhibits will be most desirable in competition for the handsome prizes which the society now offers. Groups both in the competitive and non-competitive classes were very handsome. It is pleasing to record that the greater part of the ground-floor space was occupied by Chrysanthemum exhibits, and viewed from the different galleries, presented a bright and striking appearance. The building, too, seemed to be better ventilated than usual. When it became necessary to ventilate this vast structure, it was at once apparent that special pains had been taken to add materially to the lighting arrangements, and when these were completed it was quite an easy matter both to scrutinise individual blooms and their names. Vegetables were splendidly staged. These, with the specimen Chrysanthemum plants, occupied the St. Stephen's Hall, the latter being arranged on the floor down the centre of the building.

CUT FLOWERS.—OPEN CLASSES.

The only mixed class in the numerous competitions was that for forty-eight blooms, to consist of twenty-four incurved (distinct), and twenty-four Japanese (distinct), open to Chrysanthemum and horticultural societies only. On this occasion there were three competitors, first prize being secured by the Portsmouth and District Horticultural Society, the whole of the blooms coming from the establishment of Mr. James Agate, nurseryman, Havant, Hants. His best Japanese flowers were Jane Molyneux, of

pleasing form and loose build; Mrs. W. Mease, Col. W. B. Smith, Viviani Morel, Lady Hanham, Milano, Australie, and M. Pankoucke. Incurved blooms were best represented by Baron Hirsch, Mrs. N. Molyneux, Princess of Wales, Violet Tomlin, Lucy Kendall, and Globe d'Or. The Bromley and District Chrysanthemum Society was a close second, the Japanese blooms being particularly fine, and included notable examples of G. J. Warren, Lady Ridgway, Mme. Carnot, Milano, Mutual Friend, Mrs. H. Weeks, and Chas. Davis. The incurved were less even, Globe d'Or and Robt. Petfield being the best. The classes in which the Holmes Memorial challenge cups are offered with valuable money prizes are generally well filled. For thirty-six incurved blooms, distinct, we understand that Mr. W. H. Lees would have been placed first had he not unfortunately staged Mrs. Heale and Princess of Wales on the same board. These two sorts the classification committee have decided are too much alike, and could not therefore be used in the same competition. His flowers were distinctly good and even in form. First prize consequently fell to the lot of Mr. W. Higgs, gardener to Mr. J. B. Hankey, Fetcham Park, Fetcham. These were a heavy lot of flowers, some rather rough and not so even as usual. The leading blooms were Duchess of Fife, Ma Perfection, Miss Dorothy Foster, Mme. Ferlat, J. Lambert, Mrs. R. C. Kingston, George Haigh, Princess of Wales, D. B. Crane, Mrs. Coleman, Jeanne d'Arc, Mme. Darrier, and C. B. Whitnall. Mr. J. H. Goodacre, gardener to the Earl of Harrington, secured second place with large blooms, several of which were rough and uneven in form. In the class for forty-eight Japanese blooms, distinct, which is the chief cut bloom class of the show, Mr. W. H. Lees, gardener to Mr. F. A. Bevan, Trent Park, Barnet, was first. His stands contained a large number of typical Japanese blooms, showing the very best culture. Exceptionally fine were his flowers of Surpassé Amiral, Australie, Lady Ridgway, Mme. Carnot, M. Chenon de Leche, Mrs. G. W. Palmer, Robt. Powell, J. Bidenscope, Edith Tabor, Nellie Pockett, Mrs. F. A. Bevan, Viviani Morel, Souv. de Mme. E. Rosette, Simplicity, Louise, Mrs. W. H. Lees, Col. Chase, Mutual Friend, Chas. Davis, Mrs. W. Mease (primrose Mme. Carnot), M. Hoste, Mrs. C. H. Payne, Ella Curtis, Mrs. H. Weeks, J. Chamberlain (rich crimson), Phœbus, Chatsworth, Mrs. Lewis, and a magnificent bloom of T. B. Haywood. Mr. Frederick Vallis, Bromham Fruit Co., Ltd., Bromham, was second with wonderfully fresh, clean, and large blooms of high quality. His bloom of G. J. Warren, one of exceptional merit, secured Mr. Simpson's special prize and an oil-painting of the flower itself, as being the premier Japanese bloom in the exhibition. Other sorts deserving mention were Mme. P. Rivoire, Mrs. Mease, Mrs. G. W. Palmer, Mons. Chenon de Leche, Mons. Hoste, Viviani Morel, Sec. Fierens, Mutual Friend, Swanley Giant, Viscountess Hambleton, Edwin Molyneux, Phœbus, and Chas. Davis. Mr. Mease was third. On this occasion, and for the second consecutive time, Mr. Norman Davis, The Vineries, Framfield, Sussex, won the Turner Memorial cup, this, therefore, becoming his own property. The competition was for thirty-six blooms of white, yellow, and crimson Japanese Chrysanthemums in twelve varieties, three blooms of each. Mr. Davis staged Mme. Carnot, Mutual Friend, Mme. Gust. Henri, and Mrs. S. C. Probyn as whites, Joseph Chamberlain, E. Molyneux, Dorothy Seward, and General Roberts as crimsons, and as yellow sorts G. J. Warren, Oceana, President Nonin, and Phœbus. The only other exhibitor was Mr. W. J. Godfrey, Exmouth, who also had a fine lot of blooms, and was awarded second prize. Reginald Godfrey was a striking crimson variety in his collection. To commemorate the twenty-first show held in the Royal Aquarium, the chairman and directors of the company offered valuable money prizes for twenty-four Japanese blooms, distinct. A collection of extra

excellence gained first prize Mr. R. Kenyon, gardener to Mr. A. F. Hills, Monkham, Woodford Green, Essex. The best blooms were Mons. Hoste, Master H. Tucker, Chas. Davis, Secrétaire Fierens, Lady Hanham, Dorothy Seward, Viviani Morel, Mrs. H. Weeks, Mons. Chenon de Leche, Mrs. J. Lewis, Mme. G. Bruant, Phœbus, Mlle. Desblanc, Soleil d'Octobre, John Neville, Mr. Mease, gardener to Mr. A. Tate, Downside, Leatherhead, occupying second place with a grand lot of flowers. Other open classes included one for twenty-four incurved blooms, distinct, Mr. Higgs again occupying premier position. Good examples were staged of Duchess of Fife, Chas. H. Curtis, R. Petfield, Ma Perfection, Mme. Ferlat, James Agate, Baron Hirsch, George Haigh, Jeanne d'Arc, and a charming bloom of Mrs. R. C. Kingston. Second prize was secured by Mr. W. Wilson, gardener to Mr. R. C. Christie, Ribsden, Updown Hill, Bagshot. No less than nine competitors were forthcoming in the class for twelve incurved, distinct, first prize going to Mr. G. J. Hunt, gardener to Mr. Pantia Ralli, Ashstead Park, Epsom, who staged a grand lot. Particularly good were Duchess of Fife, Chas. H. Curtis, J. Lambert, Mrs. S. Coleman, Globe d'Or, and Empress of India. Mr. W. Robinson, gardener to Lord Ludlow, Heywood, Westbury, was second with rather rough and uneven flowers. For six blooms of one variety of incurved Mr. G. J. Hunt was first for superb examples of Duchess of Fife, Mr. W. L. Farmer, gardener to Mr. H. P. Leschelles, Highbams, Windlesham, Surrey, coming second with handsome flowers of Chas. H. Curtis. For twelve Japanese blooms, distinct, premier honours were secured by Mr. W. Meredith, gardener to Mr. D. P. Sellar, Dudbrook, Brentwood, with fairly heavy blooms of M. Chenon de Leche, Mons. Hoste, Mrs. G. W. Palmer, Chas. Davis, George Seward, Mons. Pankoucke, and T. B. Haywood. A pretty, fresh and neat stand of blooms, obtained second prize for Mr. F. W. King, gardener to Mr. A. F. Perkins, Oakdene, Holmwood. Mr. Norman Davis was an easy first for six Japanese, white, one variety only, with superb examples of Mme. Carnot beautifully finished, and Mr. G. Fisher, gardener to Mr. H. Hammond Spencer, Glendaragh, Teignmouth, followed with rougher and less pretty blooms of the same variety. For six yellow Japanese, one variety, Mr. H. Shoesmith, Claremont Nursery, Woking, was first with handsome flowers of the ever-popular Phœbus, Mr. James Agate being second with neat and pretty flowers of Mrs. W. Mease. A more limited entry for six Japanese, one variety, any colour except white and yellow, was forthcoming, Mr. J. W. McHattie, gardener to the Duke of Wellington, Strathfieldsays, Hants, being placed first with grand blooms of Australie; second prize was won by Mr. W. Slogrove, gardener to Mrs. Crawford, Gatton Cottage, Reigate, who had Lady Hanham. But three entries were staged in the class for six Japanese incurved, distinct, the selected varieties winning first prize being John Pockett, Pride of Madford, President Bevan, Australie, Australian Gold and Mons. Gerard, these coming from Mr. H. Perkins, gardener to the Rt. Hon. F. W. D. Smith, M.P., Greenlands, Henley-on-Thames. Mr. John Justice, gardener to Sir Richard Temple, Bart., The Nash, Kempsey, was second. Only three stands were seen in the hairy-petalled class for six Japanese, not less than three varieties. These were a poor lot, Mr. H. Love, Sandown, Isle of Wight, showing Hairy Wonder, Mrs. Dr. Ward, Abbé Pierce, Arthur and Beauty of Truro. Mr. Justice was again second, showing a moderate lot of blooms. For the valuable prizes offered by Mr. H. J. Jones for two blooms each of Mme. Carnot, Mrs. Wm. Mease and G. J. Warren there were eight competitors, Mr. W. Mease being an excellent first with neat and heavy blooms of each sort. Mr. Higgs was second with smaller flowers. Proof of the declining interest in the reflexed blooms was again seen, only two competitors staging twelve blooms in not less than nine varieties. Mr. T. Caryer, gardener to Mr. A. G. Meissner, Alderholme,

Weybridge, was placed first with moderate flowers with little to commend them. Mr. W. Robinson was second, Miss Florence Lunn (amaranth) being the most notable. Five stands were placed in competition for the prizes offered for twenty-four large-flowered Anemone kinds, including Japanese, distinct. This was a very pretty display. Mr. W. King, gardener to Mr. James Warner, Capell House, near Waltham Cross, was a good first with an even, fresh, and clean lot of flowers. Mr. Wm. Skeggs, gardener to Mr. A. Mosely, West Lodge, Hadley, Barnet, was awarded second prize for a less even display. Mr. Justice was first out of five entries for twelve large Anemones, Japanese sorts excluded, Descartes, Flour de Marie, Lady Margaret, Lady Temple, Mrs. Judge Benedict, E. C. Jukes and Delaware being the best. Mr. W. King was placed second, also with a nice lot of blooms. Twelve Japanese Anemones (distinct), brought out six exhibitors; the stand securing first prize contained a beautiful lot of flowers of even finish and good form. This came from Mr. W. Robinson, and well merited the distinction it gained. W. W. Astor, Enterprise, Mrs. Caterer, M. Dupanloup, Sir Walter Raleigh, John Bunyan, Sœur Dorotheé Souille, and Mr. H. H. Gardner were the best examples. A pretty lot of flowers, in which were some individual blooms of considerable merit, placed Mr. W. Skeggs second. Mr. Justice again led with a nice exhibit of Anemone pompons. Mr. T. Caryer, out of five competitors, was placed first with a beautiful lot of twelve pompons, distinct, three blooms of each variety. They were not too large, were prettily set out, and embraced a pleasing variety of colour. His varieties were William Westlake, Perle des Beautés, President, Mlle. Elise Jordan, Pygmalion, La Vogue, Osiris, Mme. Marthe, Rubrum Perfectum Toussaint Marizot, Black Douglas and Mr. Holmes. Mr. W. Aldridge, Palmers Green, was second. Single Chrysanthemums made a pretty show and a pleasing variation. Those from Mr. Aldridge were a very even and well-developed lot of blooms, and well deserved the first prize. Alphonso, Admiral Sir T. Symonds, Oceana, Miss A. Mumford, Ewan Cameron, and Framfield Beauty were his most conspicuous blossoms. Second prize was credited to Mr. G. W. Forbes, gardener to Mme. Nicols, Regent House, Surbiton.

AMATEURS' CLASSES.

The leading prize for eighteen Japanese, distinct, was won by Mr. L. Gooch, gardener to Mr. T. Wickham Jones, Frocester Lodge, South Norwood, with a good lot of flowers, followed by Mr. A. Hooney, gardener to Mr. G. H. Cox, The Grange, East Barnet. A spirited competition for twelve Japanese, distinct, was seen, no less than twelve stands entering. A creditable lot of blooms secured leading honours for Mr. W. A. Brown, gardener to Mr. H. W. Sillens, The Pines, Horsell, Woking, Dorothy Seward, Lady Ridgway, Modesto and Lady Hanham being good; Mr. R. Gladwell, gardener to Mr. Sydney Smith, Wendee Hall, South Norwood, being a close second. Mr. Gladwell was first out of nine competitors in the class for six Japanese, distinct, showing a very lovely lot of flowers; Mr. W. Perrin, gardener to Mr. C. W. Richardson, Sawbridgeworth, second with Simplicity and Emily Silsbury in fine form. Mr. J. Denyer, gardener to Mr. Edwin Smith, Ingleside, Chatham, was first with Phœbus for six Japanese, one variety, second prize falling to Mr. J. Acock, gardener to Mrs. Bacon, Worcester Road, Sutton, with well coloured blooms of Vivand Morel. In the incurved classes Mr. C. E. Wilkins, Wellington, Swanley Junction, was first for twelve distinct, staging very neat and pretty blooms of Lady Isabel, Mrs. R. C. Kingston, Chas. H. Curtis, Mrs. R. Owen and Globe d'Or; Mr. A. Honey was second. For six incurved, distinct, Mr. Wilkins again led, followed by Mr. W. Leppard, gardener to Mr. F. Vigers, Oakdene, Reigate. In the class for six incurved, one variety, Mr. Honey led with neat and not over-large C. H. Curtis; and with Austin Cannell, Mr. Wilkins was

second. For six bunches pompons, distinct, Mr. W. Aldridge was a capital first with bright and pleasing examples, Miss R. Debenham, St. Albans, being second. There were five competitors in the class for eighteen Japanese, distinct, for which Mr. G. P. Linford gave a silver cup, and for which the society offered additional money prizes. First prize was won by Mr. A. R. Knight, 63, Hardinge Road, Ashford, Kent, who had a nice lot of flowers of good form; Mr. Martin Silsbury, Shanklin, Isle of Wight, was a good second with a bright display of blossoms, not quite so heavy, but of good colour. Mr. H. A. Needs, Heathview, Horsell, Woking, secured leading honours in the class for twelve Japanese, distinct, with a very fine lot. Miss Elsie Teichmann, Mrs. G. W. Palmer, Mme. Couvat du Terrail, Edith Tabor, E. Molyneux, and Lady Ridgway were his best. Second prize was awarded to Mr. W. G. P. Clark, Hitchin, showing a considerable falling off. For six Japanese, distinct, Mr. Needs was again to the fore with splendid examples, followed again by Mr. Clark. A very handsome set of six blooms of Phœbus secured for Mr. Norman Wrightson, 55, Elgin Road, Addiscombe, Surrey, first prize for six Japanese of one variety, Mr. Love showing a bronze seedling in taking second place. Mr. Knight was first for twelve incurved, distinct, with a neat and even lot of blooms, Bonnie Dundee being one of his best flowers, second prize going to Mr. J. H. Sharpe, Greenwood, Hants, Bridgewater, who followed closely, having good examples of D. B. Crane, Ma Perfection, and Duchess of Fife. Mr. Clark and Mr. Knight were first and second respectively for six incurved, distinct. The prizes for six bunches of pompons not disbudded, distinct, which were very charming, were secured by Mr. A. Taylor, East Finchley, and Mr. T. W. Preston, 8, Commercial Road, Peckham. Maiden growers were encouraged with four classes, the competition being quite extraordinary; fifteen in one class, sixteen in another, and so on will give some idea of the interest taken in the exhibition by budding enthusiasts. Messrs. H. Folke, Hemel Hempstead; A. G. Clinton, Horsell; J. Coomber, Kingston Hill; G. Hobday, Romford; and J. B. Purchase, Redhill, were the principal prize-winners.

PLANTS.

The circular groups, each 12 feet in diameter, were arranged in the south-western gallery. There was little to choose between them, the leading position ultimately falling to the lot of Mr. J. Spink, Summer Road Nursery, Walthamstow. His group was surmounted by a splendid Cocos Weddelliana, and freely mingled with handsome Chrysanthemums were other Palms, Crotons, Ferns, &c., a fringe of fine-foliaged plants giving a neat finish. A good second was found in Mr. W. Howe, gardener to Sir Henry Tait, Park Hill, Streatham, who used graceful Bamboos for the centre, and who also had a tastefully arranged group. Four trained specimens were distinctly below the average. Mr. F. E. Wraight, gardener to Mr. J. Troup, Essex Lodge, Upper Clapton, was placed first with freely flowered plants too stilly tied, second prize falling to Mr. F. Gilks, gardener to Mr. A. Morris, Court Green, Streatham, with large, rather flat specimens; Mr. J. Shrimpton and Col. W. B. Smith were his best plants. The only competitor—a beginner, by the way—in the class for six plants, large-flowered varieties, was Mr. F. Gilbert, gardener to Mr. W. A. Sewell, Fairlight, Shepherd's Hill, Hightgate, who had a fairly even exhibit. The judges awarded only a second prize. Only one competitor—Mr. Gilks—entered for six standard-trained specimens, and although freely flowered and neatly tied, this style of growing specimen plants is distinctly inartistic and artificial. First prize was awarded in this instance. Mr. Davey, gardener to Mr. C. C. Paine, Hillfield, Haverstock Hill, N.W., was first with four standard-trained specimens, Eva Knowles, Cleopatra, Stanstead Surprise, and William Tricker representing his varieties. Mr. Wraight occupied second position with a moderate lot of plants. For a single

specimen plant, Mr. Davey received second prize with an indifferently flowered Chas. H. Curtis.

DECORATIVE EXHIBITS.

Messrs. Perkins and Sons, Coventry, won first prize for a table of bouquets, wreaths, sprays, button-holes, &c., illustrating the decorative value of the Chrysanthemum. Several charming bouquets, harps, epergnes, stars, hand-baskets, and many other floral devices were perfect examples of artistic floral work. Miss Nellie Erlebach, The Florist, Stoke Newington, N., was second with a less pleasing arrangement of designs and with one or two individual illustrations of considerable merit. For three epergnes, suitable for dinner-table decoration, a light arrangement secured for Miss C. B. Cole, The Vineyard, Feltham, first prize, second prize going to Mr. F. W. Seale, Sevenoaks, for a very airy series of stands. Few of the arrangements showed a proper association of colours, which should always be the essential feature of such displays. For two vases of pompons arranged with any foliage for decorative effect, Mr. Mark Webster, gardener to Mr. E. J. Preston, Kelsey Park, Beckenham, was first, Mr. W. Green, Jun., Harold Wood, Essex, being placed second with smaller, but pretty vases of blossoms. For one vase of six blooms of Japanese flowers, one variety only, Mr. J. King, gardener to Mr. H. J. G. Lloyd, Itchel Manor, Crondall, Hants, was first with Edith Tabor in splendid condition, second prize being awarded to Mr. T. H. Lodge, gardener to Mrs. Nevet, Hockerill, Bishop's Stortford, with pretty blooms of Mrs. W. Mease. Mr. Mark Webster was again first for two superb bouquets, each lightly and tastefully finished, and Miss Easterbrook, Fawkham, Kent, won for hand-baskets. A vase of six blooms of any one Japanese variety, open to amateurs and maiden growers, brought out twelve competitors, and these in themselves made a grand show. First prize was secured by Mr. Thos. Parkins, gardener to Mr. W. F. Ward, 34, Bisbam Gardens, Hightgate, who showed a large bronze incurved Japanese variety, Mr. R. Chamberlain, gardener to Mr. F. M. Loneragan, Cressingham, Reading, following with a beautifully arranged vase of Phœbus.

FRUIT.

For three bunches white Grapes, Mr. W. H. Lees was first with beautifully even bunches and well coloured berries of Muscat of Alexandria, Mr. C. W. Cole, Feltham, securing second prize. For three bunches black Grapes (not Gros Colman), Mr. W. Howe had large, well-shaped, and beautifully coloured bunches, Mr. W. Taylor, gardener to Mr. C. Bayer, Tewkesbury Lodge, Forest Hill, S.E., taking second prize. Mr. Taylor was first for three bunches of Gros Colman, showing grand heavy bunches, Mr. F. Milcom, gardener to Mr. J. Stoddard, Forest Lodge, Tulse Hill, Brixton, showing smaller bunches, but splendidly coloured. For six dishes dessert Apples, Mr. H. Berwick, Sidmouth, Devon, was first with a bright lot of fruit, Ribston Pippin, King of Pippins, Wealthy, American Mother, and Adams' Pearmain being the best. The second prize lot from Mr. A. J. Thomas, Burgan Hill, was also a very fine exhibit. Mr. W. Stevens, gardener to Mr. G. H. Dean, Sittingbourne, Kent, was a good first for six dishes of cooking Apples, showing Glory of England, Mère de Ménage, Emperor Alexander, Lane's Prince Albert, Peasgood's Nonsuch, and Bramley's Seedling. Mr. A. J. Thomas was second with a handsome exhibit. Mr. Thomas secured premier honours with six dishes dessert Pears (fit for table), showing grand examples of Columbia, Maréchal de la Cour, General Todleben, Pitmaston Duchess, Princess, and Beurré Lamoyeau. A good second was found in Mr. H. Berwick, who had some grand dishes.

VEGETABLES.

For nine dishes of Potatoes, Mr. E. S. Wiles, gardener to the Hon. Evelyn Hubbard, M.P., The Rookery, Down, Kent, was a good first with a wonderfully even and clean lot of tubers, Mr.

Silas Cole, gardener to Earl Spencer, K.G., Althorp Park, Northampton, taking second place with a good set, but not so even as the first-prize lot. Nine entries for two dishes of Potatoes, to be selected from given sorts, found Mr. Cole to be the fore with grand examples of Supreme and Windsor Castle, Mr. H. Folke, gardener to Mr. E. Strachan, Gaddesden Place, Hemel Hempstead, with Supreme and Ideal taking second prize. The foregoing prizes were offered by Messrs. Sutton and Sons, Reading. A collection of nine kinds of vegetables for prizes offered by Messrs. Webb and Sons, Stourbridge, brought out five competitors. In this Mr. E. Beckett, gardener to Lord Aldenham, Aldenham House, Elstree, again asserted his superiority with a wonderfully fine collection admirably set up. Second prize was won by Mr. R. Lye, gardener to Mrs. Kingsmill, Sydmonton Court, Newbury, with an exhibit, although good, falling considerably short of the first-named. Mr. Robert Sydenham, Birmingham, offered five prizes in thirteen different classes for a variety of vegetables. In addition to the individual prizes, a handsome challenge cup, value 15 guineas, to be held by the winner of the greatest number of points, five points being allowed for a first prize and so on down to one for a fifth. In these competitions Mr. Beckett completely outdistanced his rivals, obtaining no less than forty-five points, thus securing the cup. The next two in order of merit were Mr. Folke with thirty-four points and Mr. Lye thirty points, each of whom received medals.

MISCELLANEOUS.

By far the most imposing and handsomest trade display ever brought together was made by Mr. H. J. Jones, Ryeocroft Nursery, Lewisham, S.E. This exhibit contained two large groups of Chrysanthemums with a large table between them, on which were Oriental vases filled with blossoms of new and choice sorts, and with which were associated fine-foliaged plants, including Crotons and other equally effective material. The front of the table contained some dozens of new sorts recently acquired, and included Japanese Dr. Hope, Mrs. W. Mease, Rayonnante, Mrs. Seward, Frank Seward, and Fred Joy. A few new incurved, including Hanwell Glory and Mrs. H. J. Jones, which variety should soon be as popular as Duchess of Fife, were among the promising novelties (large gold medal). Messrs. H. Cannell and Sons, Swanley, also had an immense table of cut Chrysanthemums and some seventy bunches of zonal Pelargoniums. At either end of the table a pretty group of bright-coloured Cannas gave a beautiful finish to their display (large gold medal). Mr. W. J. Godfrey, Exmouth, arranged an exhibit of great merit on a table crossing the building, the centre of the long table being admirably set off with vases containing a number of beautiful blossoms. Individual exhibition blooms were also freely staged, and included such sorts as Autumn Glory, a very pleasing tint of colour; Mrs. F. A. Bevan, Mrs. Mease, Ella Curtis, Le Grand Dragon, Wilfred Godfrey, President Nonin, and Capt. Bellamy (silver-gilt medal). A like award went to Messrs. J. Laing and Sons, Forest Hill, S.E., for a useful collection of coniferous plants, pleasingly grouped. A small gold medal was well merited for the handsome display made by Messrs. W. Cutbush and Son, Highgate and Barnet. At the rear were grouped Chrysanthemums in variety, while in front freely-flowered Malmaison and other Carnations were staged. As a finish, a neat edging of Roman Hyacinths embedded in Moss was particularly pretty. From Messrs. B. S. Williams and Son, Upper Holloway, a table of lovely plants secured a small gold medal. Orchids, Heaths, winter-flowering Begonias, and fine-foliaged plants, each in charming variety, formed a welcome feature in the display. Silver medals were awarded to Messrs. T. S. Ware, Limited, Tottenham, for a table of new Chrysanthemums; to Mr. John Russell, Richmond, for a splendid group of Ivies in many diverse forms and varieties; to Messrs. Peed and Sons, Roupell Park

Nurseries, Norwood, for a nice group of freely-flowered Chrysanthemums; and to Mr. Robt. Owen, Maidenhead, a silver-gilt medal for a table of splendid exhibition Chrysanthemums of high quality, among which were conspicuous Sir Herbert Kitchener, Mary Molyneux, and Lord Cromer, a grand crimson Japanese. A table of rustic table decorations from Mr. J. Williams, Ealing, was admired.

Horticultural requisites were exhibited freely and in great variety. The Ichthemic Guano Company, Lawe's Chemical Manure Company, the Agricultural and Horticultural Association, Limited, and the Permanent Nitrate Company each had a worthy representation of their wares. A number of boilers, &c., came from Messrs. C. P. Kinnell and Co., Southwark Street, and Mr. Pinches, Camberwell, showed his patent labels.

On Monday last the floral committee of this society held a very interesting meeting at the Royal Aquarium, Mr. Thomas Bevan being in the chair. There was a good attendance both of members and visitors, and the exhibits were numerous and of a high standard of excellence. The principal exhibits were staged by Messrs. H. Cannell and Sons, Mr. H. J. Jones, Mr. W. Wells, Mr. R. Owen, Mr. H. Weeks and several others. It was a noticeable feature that some of the finest specimens of incurved that have been seen anywhere this season were novelties presented at this meeting. However, nothing short of the highest quality attainable seemed to meet with the approval of the committee, and the following first-class certificates were awarded:—

CHRYSANTHEMUM MRS. W. HOWE.—A big, deeply-built incurved of the old type, with stiff, grooved, regularly arranged florets; colour, a pure deep golden yellow or chrome. Shown by Mr. W. Howe.

CHRYSANTHEMUM H. J. JONES.—This is probably one of the most brilliant Japanese ever raised. It has long loose florets of medium width. The colour is without equal, being of a dazzling velvety crimson, reverse and centre bright gold. From Mr. W. Seward.

CHRYSANTHEMUM HANWELL GLORY (incurved).—A massive-looking flower of the most perfect build. It has a multitude of narrow grooved florets, forming a deep, compact flower of great merit; colour, a deep rich shade of golden bronze. From Mr. Seward.

CHRYSANTHEMUM C. S. BORTES.—A very full, double flower of the incurved section, large and very regular in form; colour pure golden yellow. From Mr. R. Owen.

CHRYSANTHEMUM LE CHALONAIS.—A very nice form of Japanese Anemone. It has a fine disc and flat, neatly arranged guard florets; the colour is golden yellow, shaded cinnamon. Exhibited by Mr. H. J. Jones.

CHRYSANTHEMUM JOHN POCKETT.—A noble Japanese incurved of remarkable size, with big, broad incurving florets lined with reddish crimson, the reverse deep golden bronze. This came from Mr. W. Wells.

CHRYSANTHEMUM MME. GABRIELLE DEBRIE.—A large Japanese incurved with broad grooved florets, very deep and globular in build; colour pale pink. From Messrs. H. Cannell and Sons.

CHRYSANTHEMUM MADELEINE DAVIS.—A very fine form of true Japanese, with long, twisted, intermingling florets most effectively arranged. The blooms are very large; colour pale lilac-mauve, rather pinkish towards the centre. From Mr. W. H. Lees.

CHRYSANTHEMUM MISS ANNIE HILLS.—One of the big, broad-petalled incurved varieties, very deep in build and large in size, a close, compact, massive flower; colour white, slightly tinted flesh or blush. From Mr. H. Weeks.

Also very noteworthy were Mrs. Grogan, a charming bright pink Japanese, of which the committee wished to see a plant, it being shown as a decorative variety. Jalene, a noble pink incurved, and Pearl Palace, a pale flesh-coloured incurved, were also asked for again. Mrs.

W. C. Egan is another fine incurved bright rosy pink. Owens' Memorial, a rich crimson and bronze, and Mr. T. Carrington, purple, both Japanese, were also asked to be submitted again. The committee awarded a commendation to Mrs. Alfred Kimber, a yellow sport from Mrs. Dr. Ward. Mr. Witty, of Nunhead, sent some very curious and fantastic novelties which were quite out of the ordinary, one being like a small bunch of silken twisted thread, and another a peculiar long, drooping, spidery-looking flower, which were stated to be novelties from Japan. Mrs. P. R. Dunn, a large white Anemone Japanese; Yellow Eva Knowles, a golden-buff sport from Mary Molyneux, and a pretty pale yellow sport from Source d'Or were also promising.

Royal Horticultural Society.—The £10 10s. Sherwood cup will in 1899 be given for vegetables shown by amateurs or gentlemen's gardeners on June 13 and December 26. The points obtained by each exhibitor on each day will be added together for the result. June 27 will be the Rose Show at the Drill Hall. On July 11 there will be an international conference held at Chiswick on "Hybridisation and Cross-breeding in Plants," together with an exhibition of hybrid and cross-bred plants with their parents (when possible) for comparison. The next fruit and floral meeting will be held on Tuesday, November 22, in the Drill Hall, James Street, Westminster, from 1 to 4 p.m. A lecture on "Artificial Garden Manures" will be given by Mr. A. D. Hall at 3 o'clock.

The weather in West Herts.—Throughout the past week the temperatures have again been high, making this the fourth unseasonably warm week we have now had in succession. During these four weeks there has not occurred a single unseasonably cold day and only three cold nights. On the 16th inst. the temperature in shade rose to 61°, which is a very high reading for November. At 2 feet deep the ground is now about 4°, and at 1 foot deep as much as 6°, warmer than is seasonable. Since the present month began, less than half an inch of rain has fallen. The winds have again been light and the air rather damp even for November. On one day the sun shone brightly for nearly 5½ hours, but on four others no sunshine at all was recorded.—E. M., *Berkhamsted*.

Lobelia fulgens.—Have any of your readers now in cultivation the original wild plant, the parent of the splendid varieties known in our gardens as Queen Victoria, Firefly, and others? If any reader will kindly tell me I shall be greatly obliged.—S. L.

Endurance of Bamboo stakes out-of-doors.—An inquiry is made in your number of November 5 on this subject. I recollect a fence of Bamboo of some length and height in Putney Park Lane, which must have been put up more than thirty years since, and the last time I saw it it was in good order.—R. D. C.

Hemerocallis aurantiaca major.—Some three years ago I purchased some plants of the much-advertised *Hemerocallis aurantiaca major* and planted them, some in the sun and some in the shade. In October of this year I have seen the first flower. Two years ago I also purchased *Watsonia iridifolia* O'Brieni, but neither in the house nor in the open ground have I succeeded in getting a flower, though I must admit the bulbs increase and multiply. What I should like to know is, whether these failures are due to my own bad treatment or to some inherent vice in the plants.—H. S.

BOOK RECEIVED.

"Fruit Culture for Amateurs." Second edition. By S. T. Wright, Royal Horticultural Society's Gardens, Chiswick. With an appendix by W. D. Drury, F.R.H.S. London: Upcott Gill, 170, Strand, W.C.

Names of plants.—H. S.—*Tradescantia virginica*.—*Springhill*.—1, *Oncidium flexuosum*; 2, *O. tigrinum*; 3, *O. crispum*.—G. C.—1, *Andromeda floribunda*; 2, Scotch Fir, this varying from seed.

ORCHIDS.

PHALÆNOPSIS ESMERALDA.

PERHAPS no other species of Moth Orchid is so variable in the size, and especially the colour, of its blossoms as is this pretty plant. Some of the varieties are nearly always in bloom from late summer until spring, and I have noted several fine varieties quite recently flowering freely. The plants are fairly robust in habit, having leaves each about 8 inches long, and producing fine erect, many-flowered spikes. That usually looked upon as the type has rosy lilac flowers, with deeper tints about the lip, the individual blooms about 1½ inches across. Plenty of warmth as long as growth is going on and a brisk moist temperature are essential to success. I am of opinion that nearly all Phalænopsis do best suspended from the roof. Whether it is that the air is more active about the roots, or that the atmosphere is more congenial to them, I cannot say, but I have repeatedly found the best growth in suspended baskets or pots. In one collection I saw recently—where a few years ago the plants were grown on the stage not far from the glass—the improvement has been marvellous. Plants that at one time pushed small, weakly leaves are now in the most robust health, with immense leaves of firm substance, and all owing to being brought up from the stage and suspended. I am not saying, of course, that hanging plants up in baskets is going to prove a panacea for all the ills that Moth Orchids are heir to; far from it. There are scores of unhealthy plants suspended, just as there are hundreds of healthy ones grown on stages, but all conditions being equal, the plants brought up have the better chance. Important as this is for the stronger-growing members of the genus, as *P. amabilis* and *P. Schilleriana*, it is doubly so for this kind, which in its habitat is, we are told, found growing on rocks in exposed positions, where it loses its leaves in autumn and “all surrounding vegetation gets parched and dried.”

We do not copy this under cultivation for obvious reasons that have been pointed out more than once in these pages, but it is equally plain that no good can come of overshadowing such plants, while to keep them a long way from the glass during our dull, cold winters is wrong altogether. The treatment of the roots does not differ materially from that given to other known kinds. A large body of close or heavy material must be avoided, and anything in the least inclined to be sour must be removed at the time of rebasketing. Clean Sphagnum Moss and charcoal alone will grow it well, this being placed above efficient drainage. I still hold a brief for pottery ware for Phalænopsis of this class, as I believe the plants move better out of pans than cylinder-shaped baskets. The long roots are all very well as long as they are undisturbed, but when the cylinder decays and a new one is required, transplanting is not always successful. *P. Esmeralda* is a native of the islands about the Gulf of Siam, and was introduced by M. Godefroy about 1874. H.

Oncidium Jonesianum.—This pretty species I have noted flowering in several collections recently, and there are now many forms much finer than the original type. The plant flowers freely when healthy and strong. Its chief requirements are a sunny position in a warm moist house, not very large pots if so grown, and a thin, well-aerated compost. I have seen fine plants grown on lightly-dressed blocks or Tree Fern stems, but possibly the growth may be stronger in pots or baskets.—H.

Dendrobium heterocarpum.—I have noted this pretty and fragrant species in flower in several collections recently. Most of the deciduous Dendrobies are rather forward this season, the very bright and hot weather during the late summer months doubtless having something to do with this. *D. heterocarpum* is usually the first to flower and one of the easiest to grow; the blossoms occur very freely at the upper node, and are pale yellowish with a maroon-purple disc to the lip. Plenty of warmth while growing,

smallish receptacles, and a distinct resting season are its chief cultural requirements.—H. R.

Cattleya labiata R. I. Measures.—This lovely albino form is again in bloom at Cambridge Lodge, and it is certainly one of the most distinct Cattleyas that has ever flowered under cultivation. Unlike the majority of albinos, this variety has a little veining left on the lip, but it is totally distinct in colour, being, in fact, a rosy pink, quite different from the purple tinges usually seen in Cattleyas. The sepals, petals, and the ground of the lip are of the purest white, making up a chaste and beautiful flower. The habit of the plant seems exceptionally good, this being contrary to that of many of the white varieties.

Cœlogyne lentiginosa.—Though the blossoms of this species are a little dingy in colour, they show up well upon the bright green foliage and bulbs, and for this reason a few plants should be included in representative collections. The racemes are few-flowered, the sepals whitish and brown, the lip with a deep brown central ridge. In a moist, warm house and a rough, open description of compost growth is very free and vigorous. Small pieces may be suspended in baskets, but larger specimens do best in pans upon the stage. During the growing season few plants require more water, and at rest the pseudo-bulbs must not be allowed to shrivel.

Restrepia guttata—A correspondent has kindly sent me flowers of this rare and beautiful Restrepia, also the nearly allied *R. Lansbergi*. Both are lovely little Orchids, well worth attention from anyone who likes this section. The colours on the lip and lower sepals of *R. guttata* are very bright and effective, being rich purple and crimson in varying shades on a white ground. The upper sepal and petals are small and thread-like as in *R. autemifera*, from which it is distinguished not only by the colour of the blossoms, but by its stronger habit and thicker and rounder foliage. *R. Lansbergi* has very much deeper coloured flowers, the base of each sepal being a lovely dark crimson lake which tones down to rose in front, the broad part of the sepals having many dark purple spots—altogether a beautiful little blossom. Restrepias like a cool, moist house, plenty of air, and somewhat close shading in summer. In winter allow them all the light

possible, and a good minimum night temperature will be 50°. In all details of potting and watering the treatment is much the same as for *Masdevallias*.

Vanda suavis (Veitch's variety).—Among a large number of plants of this species and *V. tricolor* I lately saw, this beautiful variety was conspicuous. A fine plant was carrying two very large spikes with fourteen flowers each. Compared with the type, the flowers are very large and highly coloured, but possibly this is in part owing to the robust health of the plant. All the plants have the same vigour and the roots are pushing in all directions. It is a sure sign of well-being when the roots of these *Vandas* push well away from the centre of growth. Another fine *Vanda* I noted was *V. Parishii*, a plant that many cultivators find a difficulty in keeping healthy. The leaves are immense, one fine specimen in a large basket having seven leads, while those with single stems are finely developed. Almost every growth has a spike forming.—C. H.

Cattleya superba splendens.—Highly-coloured forms of this well-known species have been rather freely imported of late, collectors having apparently got into a good locality, and varieties labelled *splendens* are frequently met with. Some are deserving the varietal name on account of their fine colour, but others are very little removed from the type. By far the most highly-coloured form I have seen is now flowering in Mr. R. I. Measures' collection at Cambridge Lodge, both the enfolding and the front lobes of the lip being of the most intense and richest crimson-purple imaginable. The blossoms are not large, but as it is a recently-imported plant they may improve. Improvement in colour seems impossible. Few *Cattleyas* display their colour better than *C. superba*, the segments opening well back and showing the lip to great advantage. It is usually found to thrive best under cultivation in a strong moist heat with plenty of sunlight.

GALEANDRA BATEMANI.

GALEANDRAS are not so much grown as formerly, as many more easily cultivated and showier Orchids have been introduced during the last two or three decades. All the same they are pretty and interesting plants, and well worth a place in representative collections. The present species used to be freely grown, and is dwarfier than most other species. The stems only grow about 6 inches high, but they are surmounted by long, narrow green leaves, from between the tops of which the flower-spikes issue. The individual blossoms are of medium size, the sepals and petals of varying tints from deep brown to creamy yellow, the lip whitish or yellow, with a purple blotch in front. The culture of this species is often a failure, and it must be conceded that the plants are occasionally difficult to manage. Still, if care is taken with them and a few details carried out, they may be satisfactory for a few years after importation at least. Its native habitat is in Southern Mexico, where it is always found in sheltered, moist positions, not at a great elevation, as many Mexican Orchids are. Consequently under cultivation plenty of warmth is necessary, and this must be tempered by a very free distribution of water to thoroughly moisten the atmosphere. By these means, thrips—one of the worst insect enemies to this species—is kept in check, but it is the exception to see plants entirely free from this pest, which soon ruins their appearance and health. Whenever any of these are seen, or any of the brown marks on the foliage that show their presence, the house wherein they are grown should be fumigated if convenient. If not, a fairly strong decoction of soft soap and tobacco should be mixed up, and the heads of

the plants dipped in this. Sponge them carefully afterwards with clear tepid water, and syringe lightly overhead for a few days. In all probability cleaning operations will have to be repeated several times before the plants are rid of the insects, but it is useless looking for healthy growth as long as they are present. Respecting the roots, these like a fairly substantial compost, but not too large pots. Equal parts of loam fibre, peat, and Moss will suit them well, and at all times when the growth is active they must be freely watered, never, in fact, being allowed to get dry for any length of time. During the resting season, on the other hand, very little suffices, but it is a mistake to keep the plants too cool. The lighter and warmer the position in autumn, the better the growth will harden and the stronger the young leads will come away in spring. *G. Batemani* was first introduced by Mr. Barker, of Birmingham, and is named after Mr. James Bateman.

Masdevallia Gairiana.—This hybrid *Masdevallia* was raised by Mr. Seden in Messrs. Veitch's nursery, its parents being *M. Davisii* and *M. Veitchiana*. In shape it is almost intermediate between its parents, the upper sepal being bright chrome-yellow, the base thickly covered with violet-crimson papille, the long slender tail golden yellow. The lower sepals are rather deeper in colour, the violet-crimson occurring rather more freely. It was recently flowering at Cambridge Lodge, as also was *M. Measuresiana*, a pretty cross between *M. tovarensis* and *M. amabilis*. The flowers are whitish, with lines of red. The habit is most like that of *M. tovarensis*. Quite a different plant is the beautiful *M. glaphyrantha*, a hybrid between *M. infracta* and *M. Barkeana*, the blade of the flower violet-crimson, with lines of a deeper hue, the orange-yellow tail being more elongated than usual. All these hybrid *Masdevallias* are beautiful plants, of exceptional interest, and they are mostly of robust constitution and free-flowering, while most of them may be grown in one house. The requirements of the parent species as to the size of the receptacle and the compost necessary may be usually taken as suitable, while the house should be cool and very moist in summer, the glass being kept clean to admit all the light possible during the dull days.

Oncidium varicosum.—One of the most popular of Orchids, this *Oncidium* is still not so well grown as it might be, and too often the life of plants under cultivation is very short. As long as supplies are being imported, Orchid growers do not seem to trouble much about keeping the plants in health, but depend on newly-imported specimens. This is wrong from every point of view, for plentiful as any plant may be in its habitat, it becomes a question of time only for its destruction when every year sees many specimens collected and wantonly ill-used. Here, as in many other cases, overflowing is at the root of the matter, but besides this many will not take the trouble to keep the plants in health by timely and proper additions to the compost in the way of surface dressing, but let them go on getting into worse condition until a renewal of the compost becomes necessary. Then the plants in many cases are too weak to stand the disturbance. Better by far keep them healthy by anticipating their needs and attending to small cultural details as these become necessary. A native of various parts of Brazil, *O. varicosum* does well in the *Cattleya* house, where it should if possible be suspended in baskets close to the light and exposed to all the best of the air currents. Though long known, this *Oncidium* was not introduced to this country until 1848, and it flowered at Chiswick a short time afterwards.

Dendrobium Parishii.—At p. 346 "J. C. N." gives his experience with this *Dendrobium*, which is very similar to what others have found with this and nearly related kinds, such as the rather

uncommon *D. rhodopterygium*. The appearance of newly-imported plants of these two kinds gives one a fair idea of what they require, the hard, scaly pseudo-bulbs of each being evidently of quite a different texture from that of those of kinds like *D. nobile*. It is just this observation of the requirements of different species and meeting them by varying treatment that make all the difference between success and failure. *Dendrobiums* cannot be collectively treated any more than any other genus of Orchids, though many of the more popular species need almost identical treatment. The thorough ripening spoken of by "J. C. N." is advisable for all the deciduous long-stemmed kinds, though doubtless many of them flower moderately without it. The mistake that many growers make is in ripening, or trying to ripen, the stems before they are really finished. This leads to few flowers being produced owing to shrivelling of the stems during the process, and as a rule many of the blooms on such plants are small and abortive. Another point worth noting is that plants well finished and thoroughly ripened will stand being kept much drier in spring than badly-ripened ones, this being a time when the least over-watering is very dangerous.—H. R.

ORCHIDS IN BLOOM AT WEYBRIDGE.

CATTELYAS are very well done at Heath Grange, the residence of Mr. W. A. Biney. They are grown in a lean-to house facing south, where they enjoy a maximum of light with free ventilation, and they have that clean, healthy, robust appearance which characterises this genus when in the enjoyment of favourable conditions. That fine winter-blooming species, *Cattleya labiata*, is giving a nice display, the plants being so well set with bloom that they will produce flowers in succession up to January. An Orchid that with careful culture commences to flower at the close of October and remains effective for a couple of months is very valuable and should be included in the list of really useful winter-blooming plants. Its near relatives, *C. superba* and *aurca*, are well in evidence, the latter, by reason of its distinct colour, forming a complete contrast to other members of the family. One of the most delightful Orchids that expand their blooms at this time of year is *Laelia pumila*. It is, I believe, somewhat scarce and not so easy to manage as its stronger-habited relatives. It is grown at Heath Grange in a shallow pan slung near the roof, a position which seems to suit it, for one plant carries six blooms of good quality. It is a charming little species, making a display quite out of proportion to the dimensions of the plant, and should find favour with those who with but limited accommodation desire as much variety as possible. The same may be said of *Angraecum Leonis*, a miniature species, bearing flowers exquisitely pure and beautifully formed, and which afford a fine contrast to the rich colours of such things as *Dendrobium chrysanthum* and *Vanda Sanderiana*. The latter with its imposing habit of growth and handsome, richly-coloured flowers which it would puzzle a colour expert to describe is indispensable in all places where Orchids are grown to any extent. I do not know of any flower opening at this season which resembles that of this *Vanda*. No collection of Orchids would seem to be complete without the showy *Dendrobium formosum giganteum*, and I was pleased to see some good forms of *Lycaste Skinneri*, the flowers of which last so long in good condition. I remember when it first came to the knowledge of Orchid growers that this *Lycaste* could be maintained in a healthy condition in a temperature but little higher than usually given to greenhouse plants. This was in the very beginning of cool Orchid culture, and it has been proved that the plants will bloom under such treatment. I feel convinced, however, that it is happier in a higher temperature, the plants making stronger growth and the flowers opening more widely and being better in colour. In a very low temperature I have remarked that the

flowers have a somewhat contracted appearance and are rather dingy in colour. One of the most useful winter-blooming Orchids is *Dendrobium Dearei*, which produces its chaste flowers during one-fourth of the year, the pure white, green centred flowers being very attractive, as are also those of its near relative, *D. glomeratum*, the scarlet centre to the mauve-coloured blooms being a remarkable feature of this species. The quaint-looking *Oncidium Jonesianum* is so distinct as to be worthy of a place in any collection, and the same may be said of *Dendrobium Phalenopsis Schroederianum*, which exhibits considerable variation as regards the colour of its flowers.

CHRYSANTHEMUMS.

CHRYSANTHEMUMS AT WOKING.

In the Claremont Nursery, Woking, Mr. H. Shoesmith grows a representative collection, besides some plants in the open of varieties particularly suitable for outdoor cultivation. Most, if not all these seem to have been selected principally on account of their free-flowering qualities, and many of them are singularly effective and useful for the purpose. Persons who cannot for various reasons grow large exhibition blooms can easily grow such as Harvest Home, deep crimson and gold; Roi des Précoces, bright crimson-scarlet; Mme. Eulalie Morel, golden salmon; George Menier, rosy amaranth; Ivy Stark, very pretty, a golden bronze; M. Dupuis, another pretty flat-petalled golden bronze; Albert Galy, bright reddish crimson, centre gold; and Ambroise Thomas, crimson.

In the general collection of exhibition varieties Mr. Shoesmith has most of the best of the well-known standard sorts. Fine are the examples of Mrs. C. Harman-Payne, very large and bright in colour, and its two sports, M. Louis Rémy and Mrs. G. W. Palmer. Mme. Rozain is a grand incurved pink Japanese, not a modern one, but still of some value. There are also good blooms of Vivand Morel, Etoile de Lyon, Phebus, and others from various continental raisers. Modesto, a big, rich golden yellow Japanese of American origin, is very fine; so, too, is Lady Isabel, a fine pale silvery pink. Joseph Chamberlain, rich crimson and gold, and the well-known Edwin Molyneux are also conspicuous for colour. M. Ernest Calvat's seedlings, both of this and the past season, are strongly represented. One of the best is Mme. Robert de Massy, a Japanese, with a fine velvety purple-amaranth shade and a silvery reverse. N.C.S. Jubilee, Japanese incurved, pretty silvery pink; Secrétaire Rivoire, a Japanese, with long drooping florets, colour pale canary-yellow, shaded bronze, and Mme. Bertet, pure white, tinted flesh colour, are all fairly good. Among others from the same source of special merit may be mentioned such varieties as Dr. Liebert, globular and deep, colour bright rosy mauve, with silvery reverse; Australian Gold, Mme. Carnot, the curious green Mme. Ed. Roger, Le Grand Dragon, a fine new golden yellow of this season; Mme. Couvat de Terrail, a big spreading Japanese, of a pale pink, passing to white; Mme. Madeleine Expulsion, a new white; Melusine, Tatiana, Antoinette, white; Sita, white, streaked purple; M. Chenon de Lebe, Werther and one or two more. Purple Emperor is a beautiful bright plum-coloured velvety amaranth, with a silvery reverse, raised in Australia, and John Pockett, a good sized Japanese incurved, with long pointed florets, reverse golden bronze, is from the same part of the world. The massive Australie, Oceana and Pride of Madford, all well known to growers, are certainly of considerable merit. The section does not, however, end with these, for we noticed a very pretty bright crimson sport from Pride of Madford called Mabel Kerslake; Mrs. Ernest Carter, big and fine, with long drooping florets, colour clear deep primrose; Mr. T. Carrington, deep rosy amaranth, and The Convention, golden bronze. For simple beauty of colour, Miss Mary Underbay, pale soft yellow; Miss

Nellie Pockett, large white; Master H. Tucker, deep crimson and gold; and Chatsworth, a large pale pink, are all varieties from the same colony, and certainly do credit to the Antipodean raisers, who have really produced a collection of exceptional merit.

Most of the recent sports from first-class varieties of acknowledged merit are represented by excellent blooms of Lady Hanham, Charles Davis, G. J. Warren, and the paler, but nevertheless beautiful, variety, Mrs. W. Mease. Mr. Hugh Crawford is a very striking, deeply-built flower of canary yellow, and Mrs. G. Carpenter, bright rosy mauve, is another. The mere mention of Ella Curtis, Edith Tabor, Lady Ridgway, Robt. Powell, Simplicity, and Col. W. B. Smith will be sufficient to show the extent of the Claremont collection.

While giving due prominence to the popular Japanese section, Mr. Shoesmith in no way neglects the older and more formal type, the incurved. He has always been an admirer and a grower of these, and among the most forward at the time of our visit, mention should be made of some very excellent blooms of C. H. Curtis, deep in build and rich yellow in colour, Lord Alcester, Princess of Wales, very delicate coral blush rose, Lucy Kendall, bright coral-red, Mrs. Coleman, Miss Dorothy Forster, Miss Violet Tomlin, Mrs. Heale and Miss M. A. Haggas.

NOTES AND QUESTIONS.

Chrysanthemum Mytchett Beauty.—This is a pretty yellow kind, and one of the decorative sorts that has been rather prominent of late. The tone of yellow is not, however, very rich, but in the open garden at least it would prove very pleasing.

Chrysanthemum Rose Perfection.—There are few small-flowered single Chrysanthemums to equal this charming variety. A single row of clear rose-pink florets and a neatly defined disc give the blossoms, which are produced in perfect-shaped sprays, a most pleasing appearance. One spray placed in a small glass produces a fine effect, while the plant as a whole forms a freely-flowered specimen attaining a height of something over 4 feet.—C. A. H.

Chrysanthemum Clinton Chalfont.—This Japanese variety is just now in magnificent form and shows well the lateness of the present Chrysanthemum season. Growers almost without exception classify this sort as an October-flowering kind, and this has in other years been the case. There is a particular richness in the blossoms of this variety, which are of a bright glossy yellow, with a richer yellow centre. The plant is from 4 feet to 5 feet high.—D. B. C.

Chrysanthemum J. R. Upton.—This, which is of Tasmanian origin, is a large, massive Japanese flower with very long, broad, and pointed florets which twist in a pretty manner. The colour is a deep rich yellow not unlike the shade seen in Modesto, with a paler reverse. The plant has a nice sturdy habit of growth and is between 4 feet and 5 feet high. Late-struck cuttings are now developing marvellous flowers which seem to rival the yellow forms of Mme. Carnot.—C.

Chrysanthemum Madeleine Davis.—Of the many excellent novelties of this season, this is, perhaps, one of the most refined and pleasing. It is a Framfield seedling of last year, when it was thought to be particularly promising. The colour may be described as silvery white, tinged throughout with rosy violet, and on late flowers this latter colour is even more pronounced. The form is Japanese reflexed, with petals of good length, prettily twisted, and building up a flower of great depth and solidity. The National Chrysanthemum Society's floral committee awarded the variety a first-class certificate recently.—D. B. C.

Chrysanthemum Lord Cromer.—I was much pleased to read your highly commendatory remarks concerning this beautiful variety. I saw it at the Drill Hall, where the floral committee properly recognised its very pleasing form and exceedingly rich crimson colour, a hue so badly needed. Size in show flowers is responsible for the fact that collections of twenty-four, thirty-six, or forty-eight distinct varieties have 50 per cent. of them white or yellow, and the other moiety is nearly all pale hues, hardly a good rich colour being in evi-

dence. Take away the good old E. Molyneux, the newer Pride of Madford, and the still newer Mr. T. Carrington, and what of colour in a collection is left?—A. D.

ROSE GARDEN.

ROSE CRIMSON RAMBLER.

SHOULD this variety be pruned? The name certainly suggests not, and many Rose growers would ridicule the idea, and probably be dismayed by anyone suggesting it. Yet under certain conditions it is really necessary to obtain the best results. Being recommended as a climbing variety, it has been planted extensively in various positions, against walls and buildings, as a pillar Rose, and also for covering unsightly outhouses, &c. In most cases the space is limited, especially on dwelling houses and ornamental iron and wire-work, therefore the plants should be so managed that they cover the position evenly from base to summit, not only with healthy foliage, but flowers also. This desirable end, however, is seldom attained when growth is not properly regulated and young wood induced to grow up each year from the base. In the ordinary way the leading shoots soon reach the extremities of the allotted space and have to be cut back. The fact of doing so causes others to form a little lower down, and these in turn have to be treated in the same way. By repeating this operation several years growth becomes strongest where the knife is most freely used, viz., the top of the plant, leaving most of the lower part quite bare of foliage and exposing unsightly stems that support the unwieldy tops. These naturally become a mass by constant cutting back, but their own weight often causes them to topple over, they are twisted about by every wind, and not infrequently torn away from their support by gales or weight of snow.

How often is this the case with pillar Roses, and how little flower such plants produce to what they can be made to do by the proper use of the knife. To properly furnish a given space with young wood and as much as possible with bloom also it is necessary to cut a certain number of shoots down to the ground-line each year, or the evil complained of above is sure to follow. The idea that the climbing and Tea sections of Roses need little or no pruning has led many, especially amateurs, to allow their plants to grow at will, and where trained to the walls of a residence they become in a few years unsightly objects and almost a nuisance, the flowers being few and far between.

Although my remarks were intended to refer to Crimson Rambler chiefly, they are applicable to all sections of climbing Roses and other such plants generally. Two instances came under my notice during the past summer where Crimson Rambler was made to form most pleasing features and also to serve a good purpose. In one case it was planted against a continuous wire trellis about 7 feet in height which formed a background to a herbaceous border, and a division between this and the vegetable quarters. To maintain an even surface of foliage and flowers it is found necessary to cut back many of the shoots to the ground-line as they pass out of flower, and the practice answers admirably. Indeed, one could almost compare it to the treatment Raspberry canes receive, as the base of each plant forms a stool of crowns upon which sucker growth is continually being made, furnishing plenty of new growth for training to the wire screen. This young wood produces larger sprays of flower of richer colour than is usually obtained from that much older. The other case was as successful, though planted in another way and to serve a different purpose. In forming a pathway from the front to the rear of a new building down a rather steep declivity several feet of soil had to be removed, which was banked up on either side and formed slopes. This was afterwards covered with large stones and a few plants of Crimson Rambler were planted. Having a deep rich root-run, the plants made enormous growth, many of the shoots measuring upwards of 12 feet. The sprays of

bloom produced on these were correspondingly large and greatly admired. The shoots were pegged loosely to the embankment and, of course, trained lengthways. Here again it is found necessary to cut back the growth as it passes out of flower to promote new and provide room to arrange it, by which means the whole of the surface is covered with bloom in the season, which would not be the case were the plants managed differently. These are instances, I think, which prove the advantages of pruning such varieties, provided the work is carried out carefully and performed at the right time.

RICHARD PARKER.

Rose Celine Forestier.—At page 351, "P." speaks in praise of this delicate primrose-coloured Rose. It is often seen in poor condition, owing either to the roots being in an unsuitable border, or to a too close system of pruning. It is never more at home than when it can ramble unrestricted over a large area, the lateral growths merely being thinned out and shortened a little. An open light loam and a sheltered position suit it best, it being rather tender. Given the above advantages, few Roses can equal it for producing masses of bloom. Some time ago I saw a grand specimen of Celine Forestier occupying a sheltered position on the south side of a gentleman's residence in South Notts. It had grown to a great height and was profusely flowered, its chief inducements to do so well apparently being a light open border and great leniency in the use of the pruning knife.—C.

Tea Roses on own roots.—I would be very much obliged if you would kindly give in THE GARDEN a list of Tea, Hybrid Tea and Noisette Roses which do well on their own roots, or a list of such which are known not to succeed on their own roots.—R. F. J.

* * * The second part of your question is not so easy to answer, owing to the rule throughout the trade everywhere of grafting everything on the Brier or some other coarse stock, which gives rank growth at first that is not always an assurance that the plants will remain with us in the same state. We can only tell you from our experience of certain very beautiful Tea Roses which struck from cuttings in the open ground in September grow perfectly on their own roots. These are Mme. Hoste, Kubens, Mme. Lambard, Jules Finger, Gloire Lyonnaise, Bouquet d'Or and Princesse de Sagan. We have no doubt many other kinds will also be found to do, but these we have seen do. The finest Monthlies, which are very nearly allied to the Teas, always do better on their own roots, as, for instance, Laurette Messimy. It is at present rather difficult, however, to get healthy plants of own-root Roses from the trade, and the best way for you is to get cuttings put in yourself every autumn, and so gradually acquire a stock of strong plants, taking the sorts of Tea Rose and Monthlies which open best in our country.—ED.

KITCHEN GARDEN.

ONIONS.

On page 414 "A. D." remarks: "In judging Onions as now presented for show in competition, too much stress is laid on mere size or weight, and not enough on form, solidity, brightness, and clearness of skin." Having always looked upon shows as a means of fostering the production of the heaviest crop of the most valuable produce, I cannot altogether agree with "A. D." Our aim in Onion culture should always be to secure the kind of crop which will command the highest price in the market rather than set up some fanciful standard of our own to gratify the eye at the expense of the pocket. For large Onions I have always been able to command a ready sale at fairly good prices; but for small ones, even

although firm, bright, and clean, few purchasers were to be found. The large ones, if well ripened and stored in a cool, dry place, kept sound and firm into the months of March and April of the following year. In fact, an enthusiastic exhibitor once showed me some splendid bulbs in the middle of the latter month which were as firm and fresh-looking as if they had just been got ready for their first appearance on an autumn exhibition table, but which, in reality, had done service on several occasions and borne off a few prizes. Therefore "A. D.'s" sweeping condemnation in the article referred to, that bulbs "that have won prizes are rarely sound at Christmas," is out of harmony with facts. He also says, "We refuse to grant prizes to other vegetables, whether Potatoes, Tomatoes, Cucumbers, or tap-rooted kinds, simply because large." I think I am quite within general practice when I say neither are prizes awarded to Onions because of bulk or weight. What we want in Potatoes, Tomatoes, Cucumbers, tap-rooted vegetables, and Onions is size and quality (and in some instances colour) combined. Not the things which will simply yield pleasure to the eye, but those which will also augment the purse, are the things to encourage. My grievance against the standard of merit "A. D." would have set up is chiefly a financial one. In these days of low prices even for the best things, we want the greatest weight of the best marketable produce from our land, to hold our own against foreigners, and Onions are no exception. For several weeks Spaniards, with sticks loaded with strings of Onions, are met both in town and country, and the low prices at which they offer them, bid well to entirely stamp out Onion cultivation in this country. It is only possible, therefore, to survive the struggle of the fittest by producing that which will command a more ready sale than those small Spanish productions, and getting greater weight from the land than we have been doing. This can only be attained by more highly cultivating the land and securing large Onions, entailing less labour in harvesting and cleaning—weight for weight compared with small ones—and gratifying the general public demand and taste in the matter of size. By encouraging this course, in awarding prizes to the largest, best-formed, and soundest Onions, we are directing growers into the channel which is likely to aid them in holding their own against foreign competition and continuing a national industry.

ONION.

Lifting Seakale.—A fortnight ago the most matured crowns were lifted for early forcing, and when the character of the season is taken into consideration they are, I think, in a very satisfactory condition. They have been lying on the surface of the ground since being lifted with the view of giving them a rest, and will now shortly be collected and buried in soil in a convenient place, to be taken out as wanted for forcing. The main lot will be lifted in the course of a few days, and will also be buried in the same way. As these crowns will not be wanted for some time, it is unnecessary to allow them to lie on the surface, as they will force readily enough when the time comes to place them in gentle warmth.—A. W.

Autumn-sown Onions.—Complaints as to the difficulty of getting seed sown as usual in August to germinate have been general, the great drought having been inimical to growth. In many gardens so late has germination been that the plants, instead of now being strong and fit to pull if so needed, are hardly 2 inches in height, and great fear is entertained lest hard weather should destroy them. If the sowings be of the usual soft worthless Tripoli, no great harm will

be done if such a result does follow. It is most likely, however, that the plants will winter well enough. The market growers who find a ready market for strong plants of the White Lisbon in the spring will suffer most. The effect on ordinary garden production should be to make growers take to winter sowing under glass all the more freely, and thus have plenty of strong plants to put out in the spring.—A. D.

Winter-sown Onions.—A cottager who just recently showed some very handsome bright hard bulbs of Ailsa Craig, the produce of plants raised by sowing seed in a frame in January last, stated that after the present season's experience he should not sow Onion seed in the autumn again. The bulbs were about 10 or 12 ounces each, as perfect in form and as solid as well could be, and though quite small when compared with those obtained by Onion exhibitors, yet were far superior to the best spring-sown samples, and would keep well for six months. It would be well if others who want very fine bulbs of the best form and good keepers would adopt this same method of raising seedlings and planting them out into good ground. There is with such treatment no trouble in drawing drills, sowing seed, thinning, maggot attacks or other worries, and the bulbs produced are of the finest quality. Several other good varieties are as useful for this form of culture as is Ailsa Craig.—A. D.

Potatoes failing.—The interesting articles on the Potato crop which you have recently published induce me to ask for your advice. Last year I bought a small quantity of Reading Giant, and they cropped well. The tubers which I saved have this year proved almost a failure. The sets were apparently in good condition when planted in the third week in April, and at the start they appeared to grow well. Then suddenly they stopped, that is to say, the tops did not develop into that thick, sturdy growth one expects to see, and when they were dug the tubers were few and small. The (to me) peculiar and unaccountable thing was that the old sets when dug up were, except for one corner, which had apparently borne tubers, as sound as when they were planted. The land was not heavily, but only moderately manured; at planting time it was very dry, and the space between the lines was 2 feet 6 inches. Two other kinds did fairly well. Can you tell me whether my failure was the result of the season or of any fault of my own?—AMATEUR, Derby.

Onions keeping.—I have learned from a satisfactory source that by the end of October the whole of the Tripoli Onions raised at Chiswick Gardens in connection with the Onion trial conducted there during the present year had become soft and worthless. Very frequently these soft, early decaying bulbs are over and useless much earlier, in many cases even in September. But then so much is common knowledge, yet in spite of it persons will persist in advising sowing seeds of these soft varieties only in the autumn, doubtless because it has become traditional practice. Cottagers and allotment holders as well as private gardeners grow the Tripoli annually, only to find the larger portion of the bulbs decaying so early that they represent great waste. As the Chiswick trial has demonstrated that certain good selections of the White Spanish and Globe types of Onions sown in August produce not only as fine, some even finer and far more solid bulbs, the following year than the Tripoli does, but when obtained, and they ripen as early, are far better keepers. How late the best selections from the Chiswick trial will keep will later be noted and published, but quite enough of the results now are known to enable it to be clearly shown that it is far better in making autumn sowings of Onions to sow good ordinary spring stocks than it is to continue to sow the soft bulbing varieties of traditional use. Even in the matter of hardness the Tripoli was not more so than were other varieties. When, as sometimes happens, a failure follows the spring sowing of Onions, it is well to have on hand a good stock of firm keeping autumn-sown bulbs.—A. D.

TREES AND SHRUBS.

VINES IN AUTUMN.

THE charming pictures appearing in these pages show one method of cultivating the ornamental Vines. They are portraits of plants in the collection of *Vitis* at Kew, where exigencies of space preclude their being allowed to ramble at will. They are spurred back annually, just as the fruiting Vines trained to the roof of a vinery are, and during the summer they are occasionally run over with the knife, care being taken to preserve as free and graceful an outline as possible. This plan, which turns the Vine into a graceful bush, can be usefully

I do not know that anyone has ever definitely described the climatic conditions which in this country produce the most beautiful autumn tints among hardy trees and shrubs. The general impression is, I believe, that a warm, not too dry summer, followed by a dry, sunny autumn, is what is required; in other words, a good growing season, followed by a good ripening one, the latter, however, being the more important. But the curious thing is that, however good (or bad) according to this hypothesis the season may have been, some plants will prove unusually good, just as others—perhaps with a better reputation—fail. Evidently what suits one plant does not suit another even in the same genus. On the whole, the Vines have

the Narrow-water and Castlewellan Gardens. There is no doubt that the young plants have not hitherto coloured with the same uniform brilliancy as the older ones mentioned. It is, however, possible that this may be due to their youth and consequent vigour. An unduly rank or very sappy growth is certainly disadvantageous in this matter of colouring. None of our numerous planted-out specimens of *V. Coignetiae* have ever coloured anything like so well as one that was kept in a pot and consequently half starved. This year they have, however, improved on all previous years. There is no need to recommend the group of Vines generally known as *Ampelopsis*. At any rate the two best of them—Veitch's *Ampelopsis*,

Parsley-leaved Vine (*Vitis vinifera* var. *laciniosa*).

Vitis riparia.

From a photograph by Mr. G. Clumpion in the Royal Gardens, Kew.

Vitis inconstans as it is called, and the Virginian Creeper (*V. quinquefolia*)—are known everywhere as wall climbers. But there is one variety of the latter that deserves special mention as not being very generally known yet. This is the variety *muralis* (or *Engelmanni*), which differs from the old common type in clinging of itself to walls, &c., just as Veitch's *Ampelopsis* does.

I do not think the true, more woody Vines of the *vinifera* type are used so freely as they deserve to be. Their vigorous habit, often noble foliage, and the rich and varied colours many of them assume in the fall of the year ought to make a selection of them indispensable in gardens where hardy climbers are grown. *V. californica*, *estivalis* and *Coignetiae*—all of which colour a rich red when the season suits them have already been mentioned. The two last have the largest leaves, and rivaling them in this respect and in luxuriance of growth is *V. Labrusca*, which does not, however, colour well as a rule, but still dies off sometimes a good yellow. The common Vine (*V. vinifera*) in most of its forms, including the Parsley-leaved variety here figured (*laciniosa* or *apiifolia*), turns yellow. But others are amongst the best red ones; the "Teinturier" variety, for instance, turns claret coloured. *V. Romaneti* and *Spinovitis Davidiana* become a rich reddish brown; they are also peculiar on account of their bristly stems. *V. Thunbergi*, a Japanese species, generally assumes a good red colour.

VITIS AMURENSIS is perhaps the most vigorous; it is a native of North China, Amurland, &c. It is a quick, luxuriant grower, less woody than most of the true kinds of *Vitis*, the young stems and leaf-stalks having a purple tinge. It has little or no autumn colour.

V. ARIZONICA, although coming from Arizona, has proved to be quite hardy. It is a plant of medium vigour and, as will be seen in the illustration, has leaves that are amongst the smallest in the true

Vitis group. It is one of the prettiest to grow as a bush.

V. RIPARIA is another North American species, chiefly noteworthy among Vines for the charming Mignonette-like odour of its flowers; it is sometimes called *V. odoratissima*. It is quite hardy, but is not so rampant a grower as *V. Labrusca*, for instance.

V. SERIANIFOLIA, which is also figured, is one of the hardiest and most luxuriant of the *Cissus* group. As will be seen in the illustration, the leaves consist of three or five segments, these being deeply lobed and toothed. It is one of the handsomest of the cut-leaved species. It is a native of China and Japan, and is sometimes called *V. aconitifolia*.

adopted where space is limited, but it does not show the Vines in their fullest beauty. They appeal to us most when they are left to grow naturally. Not all of us have had the opportunity of seeing Vines as they grow wild, for there is no species native of Britain or even of Europe, but there is an engraving in THE GARDEN for April 13, 1895 (p. 249), "Wild Grape Vines in the Upper San Joaquin Valley, California," which shows them as they grow under sub-tropical conditions. Under our duller skies we can never hope to produce a scene of such surpassing luxuriance and beauty as that; still, it is an ideal set before us. Even a feeble imitation of it would be worth striving for.

coloured better than usual this year, but there are some exceptions. Among the American species I have been accustomed to look upon *Vitis californica* as one of the best and most regular in this respect, yet this year it has failed. On the other hand, *V.estivalis*, also American, which has not been hitherto considered to possess any special merit, has coloured most beautifully, equal, indeed, to *V. Coignetiae*, which has never been better. With regard to *V. Coignetiae*, there are still many who doubt whether the numerous plants raised from Japanese seed in this country in recent years under this name are the same as the famous Vine in the Knap Hill Nurseries or those at

Of the others in this same *Cissus* group, which does not contain many hardy species, the one known now as *V. capreolata* is, perhaps, the best coloured, its handsome divided leaves turning red. This is a native of the Himalaya and ought to have a wall to be safe. Another of the same group, *Vitis* (or *Cissus*) *arborea*, is from the United States and hardier; its doubly pinnate, handsome foliage becomes purplish red in autumn.

With regard to the autumn colour of Vines, the presence or otherwise of certain substances in the soil, such as lime or iron, may in some instances exercise a good deal of influence.

Kew. W. J. BEAN.

The Oak and Elm.—Can any of your readers afford an explanation of what I consider to be a curious fact in connection with the Oak and the Elm this autumn? In a general way, the former is much later in casting its leaves, and I have more than once noticed Oaks quite green when all the Elms hard by were denuded of their foliage. This season the reverse is the case, and it is curious to see at this late period (November 17) many Elms with hardly a discoloured leaf, whilst Oaks standing in line with them look as if a sharp frost or a gale of wind would strip them. Taking into consideration the nature of the summer, one would naturally think that the Elm, which makes its roots so near the surface, would have cast its leaves at a earlier date than usual, whereas it is, I should say, quite a fortnight later in doing so. I have more than once seen Oaks quite green in the last week in November, but it would be difficult to find one in that condition now. I have only once in twenty-five years known the Oak to lose colour before the Elm, and that was, if I remember rightly, some fifteen years ago.—J. C., *Byfleet, Surrey*.

Vitis heterophylla humulifolia.—The first time, I believe, that this charming blue-berried Vine fruited in England was just thirty years ago at Kew. For some reason, however, it has never become popular, and is really but little known, though occasionally it may be met with in good condition. Mr. Kingsmill, of Harrow Weald, has several times shown beautiful fruiting examples of this Vine, and at the Drill Hall on October 25 it again cropped up in fine condition. Yet despite the years since it was introduced and its beauty at this season, judging by the remarks overheard, it was quite unknown to the majority of the visitors. This Vine is perfectly hardy, and at the same time it is a first-rate climber for a cool greenhouse, glass corridor in a sunny spot, or any similar position. On a south wall where fully exposed to the sun it is very satisfactory, yet I find better results are, as a rule, obtained when planted in a rather narrow border than where the roots have an interrupted run. Some localities and some seasons are, of course, more favourable to its autumn display than others, the bright weather experienced during the present autumn being particularly favourable to it. Similarly the hot summer of 1893 was followed by a charming display of its beautiful bluish-tinted berries.—T.

The Sea Buckthorn.—The admirable reproduction of the fine group of this near the lake at Kew as well as the description of this fine hardy plant can hardly fail to give a much-needed stimulus to its culture. It is very seldom met with in our gardens, and yet more rarely found in such excellent condition as at Kew. No doubt one reason of this is the fact emphatically noted by Mr. Bean that the plants are of very unequal merit, the male plants being relatively unattractive. In raising the plants from seed, too, it has been complained that the males largely predominate, and there seems, as Mr. Bean says, no certain way of identifying the plants' sexes in a young state or until they begin fruiting. Many may reply, why not then propagate this strikingly beautiful plant only or chiefly from cuttings?

But this is easier said or written than done. I do not say that it cannot be done, but the process is slow and uncertain excepting in the case of root cuttings. The plants, however, are pretty fruitful of suckers and can also be propagated by layers. Probably were a brisk demand to arise for Sea Buckthorn, our enterprising nurserymen might take the trouble to prove the seedlings and guarantee the stocks they offer.—D. T. F.

LAURELS.

No other evergreen shrub gives such a pleasing effect during the long winter months as the several types of the common Laurel, especially when in masses or groups. Here a considerable area of ground is planted with them. I cut them over table-shape once a year in August and September. The plants are about 4 feet high when cutting is finished. Some judgment is needed in cutting so as not to get the surface merely a mass of snags with green points. The knife wants letting down and the branches here and there cut back, say for 18 inches. This causes a constant supply of young growths and allows the sun and air to get into them. One drawback with these masses of Laurels is that they are liable to be killed down, say once in twenty years or so, by the periodical zero winters we get in the north, though they generally break away again from the old stools and in a few years are at their usual height. Many persons condemn this mode of garden decoration both on the ground of its formality and the labour and expense in connection with the annual cutting. I do not think it is applicable in every case. Here it falls in admirably with the style the grounds are laid out, and after looking at the matter from all the standpoints I can think of, I certainly do not see any other way of planting that would come up to it here. As to the expense, it would certainly cost more if the area now filled with Laurels were laid down in grass lawns.

My main object in penning this note is to say how much better the giant or Magnolia-leaved, Caucasian, and round-leaved or rotundifolia varieties of Laurel are than the old common Laurel. During the past fifteen years I have always used one or other of these three varieties when planting Laurels. The first-named one is a splendid variety where a good bold effect in uncut groups is required. As you will see by the shoot sent herewith, it does not belie its name. Quantities of leaves made this year are 9 inches to 12 inches in length by 3½ inches to 4½ inches in width. The foliage and general habit of the second-named are much more characteristic than in the ordinary common Laurel, and I am assured by Mr. Gray, the experienced manager at the York Nurseries, that both it and the rotundifolia variety are more hardy into the bargain. For forming a bold margin to a long, straight road or covering sloping banks with a low carpet of pleasing green, the last-named variety is the best evergreen shrub I know.—H. J. C., *Grimston, Tadcaster*.

* * * *The system described by our correspondent is, unhappily, seen in almost every country place, and there is no way which is more against beautiful gardening and variety of flowering trees and shrubs. It is not only that their "table" shapes are ugly and the labour connected with them ignoble—in one place we know of nearly ten acres of Laurels cut down to "table" shape—but we have to think of the many beautiful things they keep away. Their presence and that of a few other common shrubs are a clear cause of the absence from so many gardens and shrubberies of most of the beautiful flowering trees that have been introduced, and of much ugliness besides. As our correspondent himself shows, the Laurel is not even hardy. No plant whatever is right cut in "table" shape or any other ugly or absurd form. If we want Laurels, let them take their natural form—a very fine one. It is also a very common and ignorant way to plant Laurels, a medium-sized tree naturally, where we want low shrubs, say not over 4 feet or 5 feet high—hence the need for the constant*

mutilation of the Laurel and annual labour for no end but ugliness.—ED.

The Maiden-hair Tree.—Totally distinct from any other tree hardy in this country, and beautiful in all stages and at all seasons, the fact remains that it is very rarely met with, though it should certainly be more frequently planted for ornament than it is, as, apart from other features, the peculiarly shaped leaves, from which the name is derived, are singularly interesting. These leaves during the autumn assume a bright golden yellow tint, without any of the shading of reds or crimsons which are so common. It is particularly valuable for planting as a lawn tree, its various distinctive features being then brought prominently forward. It was introduced into this country over a century ago, and occasionally a good specimen may be met with in some old-fashioned garden. The Maiden-hair Tree was always regarded as a native of China and Japan till Professor Sargent made his journey to the latter country in the autumn of 1892, when he arrived at the conclusion that it was only cultivated there, never being found in a wild state. It occurred always in the neighbourhood of the Buddhist temples, being probably brought there by the priests. Some of the specimens are said to be fully 100 feet high, with tall, massive trunks 6 feet or 7 feet in diameter.—T.

Tecoma radicans.—This I had great trouble with at first in my Suffolk garden. Knowing it was a gross feeder I planted it in a rich border against a wall. It lived, but never made any growth, so after two or three years I dug it up and planted it against an old potting shed in the gravel path, which some few years before had been heightened to make a slope to a door just cut in a wall at the side by the addition of quite 3 feet of chipped and broken tiles, and covered over again with gravel. It took my gardener half a day with a crowbar to make a hole for it. This I had filled up with some garden soil and the *Tecoma* planted. It now covers the whole potting shed, and has a main stem as thick as my leg, and is a splendid sight every year. It faces S.E. and is sheltered from the north. Every spring I prune it close like a Vine, cutting all the last year's spray off back to a good bud, and it then produces a dense mass of shoots, each clothed with a bunch of its fine flowers. It seems to like its stony quarters, for root suckers come up through the path very often. I had a good deal of trouble in propagating it till I laid some of the spring-pruned shoots lengthways in a trench at the foot of a greenhouse front wall, and then some time after I found that they had rooted at the joints and had sent up from each a plant. By this plan one can propagate it wholesale.—H. D. PALMER.

NOTES & QUESTIONS.—TREES & SHRUBS.

Weigela rosea.—No pleasure ground or public garden is complete without a few specimens of this tree-growing, profuse-flowering shrub. Young plants quickly grow into dense bushes and add quite a charm to the shrubbery border in May. The delicate rose-coloured blooms are produced on long curved shoots, these having a charming appearance when placed in tall glasses or vases with a little of their own green growth added. Weigelas are not particular as to soil if well drained.—C.

Destruction of a forest.—There is great agitation in the Commune of Mentoulles, near Pinerolo, in the Alps, at the decision of the Municipal Council to sell the adjacent forest of Chambon in order to pay the debts of the Commune. The inhabitants of the Commune are opposed to the sale of the forest, which has so long protected them against avalanches and floods. This seems to be an instance when the Ministry of Agriculture could intervene to prevent the destruction of these invaluable alpine shields against torrents and drought. Every autumn large districts of Italy are inundated, and immense quantities of valuable property

destroyed by floods due to the overflowing of mountain torrents, which would never have gone beyond their banks had not the trees, which formerly absorbed a great proportion of the rainfall, been wantonly destroyed.

ORCHARD AND FRUIT GARDEN.

NOTES ON PEARS.

In dealing with Pears I will first give the varieties which I have found at Gammersbury to do best. The Pear season commences with Doyenne d'Été, of which one tree is quite

change. The next, and always a good Pear, is Louise Bonne of Jersey. It crops and colours well with me on tall pyramids. Marie Louise and Thompson's are the next to ripen, both about the same time. Beurré Superfin, one of the best of Pears, succeeds these, being in its season a decided acquisition. Pitnasten Duchess is ripe also at the same period. For early November use Beurré Diez is one of the best kinds, being as a rule free from grittiness. Doyenne du Comice—the prince of Pears, in my opinion then ripens; in fact, I have it ripe much earlier from south walls. Then I get Beurré Clairgeau, and that much better in flavour than it is usually found. It ripens a

rarely ever fail to yield a heavy crop of fine fruits, some being in grass and others on tilled ground.

In some instances Pears will thrive better on light land than Apples, whilst, on the contrary, I have noted them in Sussex as doing better on heavy land than Apples. The kinds which I there noted as the best for heavy soils were Marie Louise, Glou Moreceau and Easter Beurré; to some this may seem singular, but it was none the less a fact. I never saw better fruits of either of these Pears in any other garden, the Pear stock being the rooting medium. The largest and most prolific trees at Gammersbury are also on this stock. I have,

however, some cordons and other trained trees on the Quince which are thriving well. In my case the merits of these two stocks appear to be pretty equally divided. My old trees, some of which are large and healthy and still bearing heavy crops, are no doubt on the Pear stock. Young trees, however, on the Pear stock do not bear so freely whilst young. On the Quince, however, the trees arrive at maturity much sooner.

I think for small gardens I am quite safe in advising that trees on the Quince stock be chosen; the growth is not nearly so luxuriant, whilst it is also easier and safer to keep the trees restricted in size. For orchards the Pear stock is, I consider, preferable; so is it on dry or poor soils. The Quince itself is usually found thriving best in moist places; this points to the fact that as a stock for Pears it should in this respect receive generous treatment. In deep soils I should also advise the Quince rather than the Pear as a stock. I well remember that the late Mr. Wildsmith was a strong advocate for the Quince stock, and he proved his point by the fine fruits he used to show from year to year. Pears on the Quince will bear more pruning than those on the Pear stock, from my own experience, and I doubt not from that of many others also. Whilst on the point of pruning, I would like to add a note on the peculiarity of Josephine de Malines in fruiting from the terminal buds. Long shoots of this Pear will often develop fruit-buds at and around the apex of each shoot. The moral, therefore, is not to cut these away; this is my practice, the pruning being

Vitis arizonica. (See p. 425.)

Vitis serrianaefolia. (See p. 425.)

sufficient. It comes into use about the third week in July. Good samples of it are a pleasing change for the dessert, but small ones are poor. To prolong its season a few days, the gathering had better be done at different times. Jargonelle follows it by a little manipulation in gathering early, and afterwards at intervals. This Pear takes the season on to about the third week in August, when Clapp's Favourite comes in, this being in its turn followed by Williams' Bon Chrétien, which also should be gathered at intervals. Souvenir du Congrès fits in here; it is best-flavoured, I find, from double-grafted trees. Beurré d'Amulis comes next, being quite a distinct and agreeable

little later with me than with some, being from a pyramid tree. The next Pear in order of ripening is Josephine de Malines; this variety, on the contrary, ripens earlier with me than in many gardens. This Pear is generally fit to use quite early in December, and it continues in season over Christmas, well into January as a rule. Glou Moreceau ripens at nearly the same time, but it never lasts so long in good condition as Josephine de Malines. To succeed this Pear I rely entirely upon Beurré Rance, of which I rarely ever fail to secure a crop of fruit from tall pyramid trees. The one most reliable stewing Pear is Catillac, on the Pear stock; these are very large, healthy trees, which

merely the thinning out of the weakest wood. The weight of the fruit upon the points of the previous year's shoots bears them down, and this induces plenty of flower-buds to form for the succeeding year. To those who have grown this Pear, but not so successfully as they could desire, I would advise the planting of standards rather than any other form of tree. When I first went to Gammersbury I found several Pears of a non-fruiting character. These were on the Pear stock, and very rank in growth. I soon found that neither summer pruning nor winter pruning was likely to be efficacious, so I almost gave it up, letting the trees (pyramids) run away freely, merely thinning out weakly shoots.

This soon had its results in heavy crops of fruit, and from that time to this those trees have borne well. As an instance of how unproductive these trees were, I would state that for two seasons or so I could not find out what some sorts were, as they were not labelled. This rank growth, aggravated by the application of an exceedingly heavy crop of manure during the spring previous to my taking charge, had its natural results in canker, and that to a serious degree. By allowing freedom of growth, however, the trees in the course of a few years grew quite out of this disease, since which time it has not given any further trouble. In another case I adopted a very radical and peculiar system of pruning. This was upon an old horizontal-trained tree of Jargonelle, which, by the old labels on the wall, must have been planted early in the present century. The branches of this tree were perfectly barren and useless, so I saved them all off close to the stem, thus leaving only the erect portion. The next season strong shoots were sent forth from the top, and in a few years I commenced to take good crops of fruit, and have never failed a crop, more or less heavy, ever since. I did the pruning once and for all when I sawed off the branches at first. Instead of the pruning-knife, now the crop of fruit does the work. In another instance I once saw and had charge of a tree of Jargonelle, which was also originally a horizontal-trained example. By reason of its paucity of fruit-buds the shoots were trained downwards from each spur, but the results thus achieved were but little better.

Now that cordon-trained trees are to be had in quantity, and that at cheap rates, no bare wall space need be unoccupied very long. This is a good plan for quickly furnishing a wall with trees that will in two seasons or so begin to give a return. I have some wall space covered now at 2 feet apart, but as the trees have reached the top of the wall I intend to incline them more obliquely, as the distance apart now will permit of some little reduction. Cordons are also admirable for arches over garden walks, in fact they are most convenient in many ways, and so are cordon Apples, besides using them as edgings. Besides the cordons of one or two stems, there are the "gridiron"-trained trees, to which I am rather partial, as they afford a little more capacity for root action than the single cordons. Espaliers, again, as in the case of Apples, are excellent so as to economise space, preferable, I consider, for narrow borders to pyramidal-trained trees. Where pyramids are grown a wider border would be better. This will allow of manipulating the trees as may be found necessary, as for instance when the shoots are pulled downwards, so as to form drooping pyramids, which I deem a better method than the semi-erect. Standard trees for gardens are not much to be commended, but I have found that Catillac is best grown as a standard. With me it is thus in every way most satisfactory. To my mind there is money in this fine stewing Pear if grown for market extensively. It is with Pears as with Apples, if any variety is not satisfactory regrafting can be performed when the parent stock is healthy. This can be done with any form of training. I have known large horizontal-trained trees to be cut back within a foot of the main stem and then be grafted afresh. In doing this it is a good plan to select those which do best when double grafted, as in the case of Easter Beurré, Jargonelle, Thompson's, Souvenir du Congrès, Triomphe de Vienne, and Passe Crassane. I have no doubt many of us have taken note of how well some Pears have borne when trained downwards from the top of the wall, the trees

being on the other side. This points, I think, clearly to an extension of this system when other means fail to produce crops.

LATE PEARS,

i.e., those which ripen from the middle of December onwards, need all the sunlight possible to properly develop them whilst still hanging upon the trees. On walls, therefore, these should have favourable positions in furtherance of this object. The same ends may, however, be gained from standards and pyramids, the point aimed at being medium-sized fruit rather than large examples. I have had very clear proof of this myself in the case of Beurré Rancee, which, in some gardens, does not ripen, hence, although not wasted, it has to pass through the kitchen. My trees of this late Pear are tall ones, hybrids between standards and pyramids; originally they were the latter form, I think. These trees never fail to crop since I got them through the canker; the fruits are of medium size, inclined to small, perhaps, but they never fail to ripen at least 80 per cent. of the crop. To some growers this might seem strange as contrasted with wall trees from whence the larger fruits are mostly taken. I think, however, I can give a satisfactory explanation. Late Pears have to arrive at maturity whilst on the trees, when the influence from the warmth of the sun is daily declining; therefore, if the fruits be large this influence upon each fruit cannot be nearly so effectual as upon the smaller ones. The latter become much better developed from this cause, I am quite positive. In support of this I would quote the Channel Island Pears of the latest kinds; there these are larger, it is true, but the ripening is brought about by more favourable climatic causes than in our case. To quote the experience of the late Mr. Wildsmith again, I would observe that he was surprised to see how well my Beurré Rancee ripened, whilst with him it was used for stewing. Whilst on the point of the ripening of late Pears, I would state that it needs a little more warmth to properly finish them than what is the average temperature of the fruit room. To accomplish this, I advise that they be placed in boxes and removed to another room or house where the temperature is between 50° and 60°, still keeping them in the dark, thus avoiding evaporation in a measure. Grittiness in some kinds of Pears detracts from their otherwise excellent qualities. Beurré Diel is a case in point at least it has been so with me. It took me a few seasons to reason this out, but I have, I think, found a remedy. In warm and even the average of summers I have noted this failing repeatedly. Then we had a wet season or two intervening, and Beurré Diel was not nearly so gritty as usual. This would seem to be contrary to theory, if not to practice, but I think it is not so. In my case I am quite convinced that this failing is brought about by drought at the roots. I have proved this to my satisfaction by watering the trees heavily once or twice (*i.e.*, large trees) when most needed during the swelling of the fruits, and in so doing have greatly reduced this defect. Whilst on the subject of

WATERING,

I will take note of this work in general as regards Pears, which I believe suffer sooner from drought than Apples. If the Quince be the stock, watering should have even more attention paid to it than if it be the Pear stock, as the former roots nearer the surface. When labour and water are both at a premium, the next best remedy is mulching; in fact, I would advise its extended application for the Quince stock, more

especially for the younger and more recently-planted trees. Another method of watering which I have adopted has answered well; it is that of applying the liquid manure from the farmyard when the cesspools have to be emptied; this I have done at quite different seasons and have been satisfied that it was beneficial.

NEW PEARS

call for a few remarks. Of these I have not personally had much experience, being rather shy of trying new kinds extensively whilst we have a wealth of good ones already. Of Marguerite Marillat I can speak favourably; it is a large and highly-perfumed Pear, something in the way of Souvenir du Congrès, but of decidedly better flavour. It is a September or early October variety, and will, I think, soon make its way into good collections. Emile d'Heyst, if not of such recent introduction, has at any rate come more prominently into notice during the last few seasons. It is of first-class flavour and the tree is hardy, whilst it crops well. Conference is another recent introduction; this also is a most promising Pear, of excellent quality and very productive. Its season is with me from the middle of October from a south wall. In dealing with both Apples and Pears I have not alluded to what may be termed fancy training. To see this art carried out in perfection one needs to visit the Continent. At both Ferrieres and the School of Horticulture at Versailles these methods are adopted, and at other places also no doubt, but it was at both of these where I saw it practised. To enter into descriptions now would occupy too much time. It suffices to say that with those who adopt it, it is a work of patience and no doubt of love. More symmetrical trees I have never seen than in these two gardens. I have noted in England, however, that the vase shape of Apple trees as developed by the Messrs. Rivers and Son is to all appearances very practical and suggestive. J. H.

Pear Thompson's.—Noted as it is for its high flavour and excellent quality, this Pear is always welcome at the dessert, and when scarce, or if the trees fail to bear altogether, there are sure to be inquiries made as to its non-appearance on the table. Generally speaking, it is a very consistent cropper, and this year has proved no exception, one fine dwarf bush tree having been heavily laden with fruit. Like several other kinds of Pears, it has ripened somewhat earlier than usual, which might have occasioned a glut, but this is not a matter of any great moment here, as the demand at this time of the year with me is usually a heavy one. I always think that the flavour of this variety is unlike that of any other Pear. I formed this opinion some twenty-eight years ago when I first tasted it, and have never since had any occasion to modify it.—A. W.

Pear Duchesse d'Angoulême.—Plenty of warmth is requisite to bring out the good qualities and ensure the highest flavour in many of the Pears which find favour with cultivators in this country, particularly those of French and Flemish origin. The past few seasons have been very favourable for the ripening of such Pears in this respect, and perhaps none more so than the one we have so recently passed through. The flavour of most, if not all, Pears that have ripened up to the present time this year has been first-rate, which remark also applies to the variety mentioned in this note. The great heat has, perhaps, been the means of hastening the ripening in this particular instance, and so caused it to come into use somewhat earlier than usual; all the same, the quality and flavour are excellent. Duchesse d'Angoulême is rather an uncertain Pear, for, as has already been hinted, much depends upon the season. In an ordinary season, to say nothing

about a wet and cold one, the fruits of this variety are then only half melting, or at the best gritty—at least such is my experience. On the other hand, where the season is a warm one and there is an abundance of sunshine, the flesh is melting and free from grit. I find it to be much more satisfactory as a bush on the Quince than when grown in any other way, even when afforded the protection of a wall. If it is only in favourable seasons that it can be had in first-rate condition, it is such an excellent Pear that in spite of this drawback it is certainly worth growing.—A. W.

Pear Alexandre Lambre.—The almost tropical heat of the past season has suited this Belgian-raised Pear to perfection, as I never remember it being so large or of such excellent quality. I added it to the collection some few years ago with the view of testing its merits, as so many foreign-raised Pears, though satisfactory as regards size and appearance, are very deficient in flavour, and the cultivation of a good number has in consequence been abandoned. The trial of Alexandre Lambre, however, proved very satisfactory, as the fruits, if somewhat small, were well flavoured, and have continued to be so each year since the tree came into bearing. This autumn the quality is exceptionally good, and the fruit almost equals Marie Louise in richness of flavour. In two leading nurserymen's catalogues it is spoken well of and described as being good flavoured, which opinion I quite agree with. It is also a very good cropper. The fruits are as a rule medium-sized and regularly formed, having a pale yellow skin strewn with irregular patches of russet. It is a vigorous grower, and soon forms a good tree, the tree I have being a loosely-trained pyramid and worked on the Quince stock. For warm localities it can therefore be highly recommended as being a good sort to plant with every chance of success.—S. E. P.

WHAT BECOMES OF NEW MELONS?

It would be extremely interesting to know how many new Melons have been placed before the fruit committee of the Royal Horticultural Society during the last, say, ten years and have received recognition in the shape of a first-class certificate or award of merit. It would be still more interesting to know what has become of them all. The latest additions I see are Wythes' Scarlet and Gunton Scarlet, which received honours on October 11. Admitting that Melons must be distinct and good before receiving recognition at the hands of a board of experts, it is surprising how little is heard or seen of the majority of them afterwards.

At most of the meetings during the season several Melons are put up for certificate, and generally one or more awards are made. With a few exceptions, out of the large number of presumably new varieties that have received recognition during the period stated little or nothing more is heard of them, and such an old standard sort as Hero of Lockinge yet remains unsurpassed. The Melon appears to be a very accommodating plant, ready enough to break away from its old character and produce seedlings of more or less variation. But after all there is little stability about it, and new Melons have become so common that they occasion little or no comment. Supposing every Melon certificated during the past ten years had remained true to its character and kept up the quality presented at the committee table, there would have been variety enough to mystify an expert. But it is very evident that they do not, or otherwise there must be scores of first-class varieties hiding their lights under bushels somewhere. The question that naturally suggests itself is whether after all there is much gained by the introduction of so many new varieties of Melons. Few of them retain their character and good qualities, or they would not fall so quickly into insignificance, and probably it would be better, instead of granting an award from the flavour of one or two fruits, to insist on the variety having a fair and reasonable trial in cultivation

to prove the worth or otherwise of the sort, whether it is sufficiently distinct, and whether its growing and cropping habits are good enough to merit it being classed as a new and distinct variety. Under the present system, season after season presumably new kinds of Melons are shown, honoured with a name and an award, and then go their way, some few to keep their reputation, and many others to be heard of no more. Nothing could be more disappointing for a gardener to obtain a new variety that has received an award and has been highly spoken of and to find when he grows it that its character is not what was represented. G. H. H.

NOTES ON PLUMS.

IN THE GARDEN (p. 306) "W. S." has not over-estimated the value of the Plum in a private garden, and it would be well if not a few gardeners devoted more wall space to it, especially when it is taken into consideration the length of time good Plums may be had. In early seasons Plums can be had ripe enough for tarts by the middle of July, with an unbroken supply up till the middle of November. On referring to my note-book, I find I gathered ripe fruit of Early Prolific on July 18 from a young tree on a west wall. No doubt had this tree been on a south aspect the fruit would have been several days earlier. This was followed by Early Orleans, Jellerson's, Kirke's, and kinds named by "W. S." with several kinds of late Gage and Magnum Bonum from north wall. Goliath hangs well on north aspects. To follow these I have several trees of Coe's Golden Drop. These I have on east and north walls, as also in a cold Peach house. I gathered the last fruits (several dozen) from open walls on October 14, as the wasps and rain were damaging them. Now (October 19) I have some hanging in a cold Peach house. The fruit from the open wall is placed in air-tight boxes in a cold, dry room and will keep a long time. Ickworth Imperatrice I have still hanging on a young tree on a west wall. Coe's Late Red is a poor crop this year. Monarch is this year first-rate. My tree is young, and grew strongly for two or three years. I lifted it and replanted it in a fresh position, and the crop was enormous. I began gathering from it in the middle of September, and now (October 19) have two or three dozen, which are useful for cooking. This does not keep so well as Coe's and several others. I am at one with "W. S." regarding the value of Victoria. I am convinced there are far too many of this and other soft mid-season kinds grown. Mr. Crawford speaks of Pershore. Would he kindly say if he has seen this grown extensively away from the midlands? I saw it in Worcestershire, and obtained trees, planting them in a garden in North Hants, but they would not thrive. I once saw Diamond bearing enormous crops in a small nursery at Chobham, Surrey. JOHN CROOK.

Popular Apples.—On taking a more leisurely look round on the second day of the Hereford fruit and Chrysanthemum show, it was rather remarkable to note how frequently four particular sorts of Apples were exhibited in the collections staged in the various divisions, consisting of from six to fifty dishes. The four sorts were Blenheim Orange, Cox's Orange, King and Ribston Pippins, and they were shown in magnificent form, too, both as regards size, quality, and great depth of colouring. The fact of either, or all, being so very frequently selected by exhibitors proves how immensely popular these varieties are, and how much they are at home in Hereford, where large quantities are grown for market. It should also, in justice, be stated that a dish of Cox's Orange Pippin was awarded the prize for the "best dish of dessert Apples in the show."—A. W.

Pear Beurre Hardy.—Birds, particularly tomtits and robins, are very fond of this Pear, and unless netted they soon make holes in and completely spoil a great number of fruits in a few days. This is no doubt owing to the flesh being very

sweet, even when quite hard, and so sure as the birds make a beginning, wasps and flies quickly follow and soon demolish the fruits so attacked. As a hardy and prolific sort for general cultivation B. Hardy can hardly be surpassed, while its large size and handsome appearance at once arrest attention. It can be highly recommended as a fast grower, and on the Pear stock either bush or pyramidal-formed trees quickly attain to large dimensions. Worked on the Quince and grown in cordon form on a wall it is equally prolific, and the fruits in this case are generally very highly coloured.—W.

Apple London Pearmain.—Under this name a very handsome even and medium-sized Apple was included in several collections at the Hereford fruit show recently. On making inquiries I find that it is known in but a few districts in the county, but it is very highly thought of by those who grow it, one grower informing me that he intended working up a good stock of it. There is not the slightest doubt that it would make a fine market dessert Apple, as the colour is so much brighter than in the Herefordshire Pearmain, which it somewhat resembles in shape. I tested the flavour, and the fruits were firm and solid when handled, a pretty sure indication that the flesh is firm and crisp eating. On referring to the "Fruit Manual" I find it is accurately described therein, but the name of the raiser and the date of introduction are not given. I imagine, from the fact of its having been so described by Dr. Hogg, that if not generally known it must have been in commerce some considerable time. Perhaps some reader of THE GARDEN can throw light on the matter as to the origin and introduction of this variety.—S. E. P.

Apple Reinette du Canada.—I recently noted some very fine specimens of this useful Apple at Livermere Park, and could not help thinking what a pity it is that this variety is not in more general cultivation. The fruits are large, flattish, with a bronzy tint on the exposed parts, and, being very firm in texture, it possesses keeping qualities beyond the average. It is a well-known fact with those who have to keep the kitchen supplied that during the earlier months in the year there is a difficulty in getting really good sauce Apples. This is a free-bearing good all-round kind that just fills the blank, and would not be out of place on the dessert table if good-flavoured kinds are scarce. The fruit, like that of many late-keeping kinds, is, I think, better for remaining on the tree until quite late in the year, as it afterwards keeps more plump. My experience of it in these gardens is limited to an old tree untrained, but, judging by the style of growth, it should do as well as any on restricted trees, and is therefore suitable for small gardens. I am planting pyramids of it this season, and I am of opinion that it will prove very useful. Free-trained trees, wherever there is room for their development, give the best results, but where espaliers must be grown this ought to be one of the varieties.—H. R.

Pear Beurre Superfin.—I have a double grafted tree of this variety which invariably bears good crops of extra fine fruit, which greatly differs from that of the ordinary Beurre Superfin both in appearance and flavour. The skin in this case, instead of being pale brown and russety, is pale green, with a few russet patches distributed about it, and it is regularly dotted over with light brown russet specks. The flavour is neither that of Beurre Superfin nor Knight's Monarch, but midway between the two, and is very rich and refreshing. This change has been brought about by working scions of Beurre Superfin on a well-established tree of Knight's Monarch about fifteen years ago. It is from the latter variety that the variation in colour and flavour has undoubtedly been derived, and the only resemblance the fruits bear to typical Beurre Superfin is in the shape. I included a dish of this Pear in the first prize collection of twelve dishes exhibited at the Hereford show on November 1, which, as one of the judges told me afterwards greatly perplexed them on account of the

colour and markings on the skin being so entirely different from those usually seen in this variety. This tree always bears more heavily and regularly than single grafted trees, while the individual fruits are larger. Whether the same results would be obtained if the experiment were repeated in another part of the garden I am unable to say, but the above is a marked instance of the influence of the stock upon the scion, whilst it also serves to illustrate the value and the benefits that are to be derived from double grafting Pears.—A. W.

FIXING CLIMBERS AND FRUIT TREES TO WALLS.

THE value of climbing plants now in our gardens is so great, that the best mode of attaching them to walls is a question which, though it may seem a small one from some points of view, is important, and by no means settled for the best. In our self-styled scientific age—the age also of the galvanised iron church and the ironmonger's fence, which is no fence—our gardens have been invaded by galvanised wire, which for a long time past has been put up on garden and house walls, and is thought to be essential in all new work. The question does not merely concern walls for climbers round the house, but also the fruit garden. As in our cold country we cannot ripen the Peach or the choicer fruits without the aid of walls, galvanised wire is used in many gardens. But many growers discover that its effect on the trees is not good, and there is a foundation of fact in these complaints common to French and English gardeners. In France, where the cultivation of wall fruit to supply the market with Peaches and fine winter Pears is carried out well, the best growers are against the use of galvanised iron wire, and where it is used it is in stout lines along the wall, so as to tie wooden rods to it. This to some extent neutralises the disadvantages of the galvanised wire, but some growers object even to this use of wire, and think it much better to have the wooden trellis only against the wall: so they keep to the older and prettier way of wooden trellis-work. For those who care about effect this is well, for whatever harm the wire may do to the tree, of its ugliness there can be no doubt. The old French and English way of fixing branches to walls—having the trellis-work made of Oak in about 1-inch strips—was a very good one. Chestnut, too, was used, and was by some thought to be the best, and is often used now in France. There, too, in the training of fruit trees, small Pine rods, half an inch square, sometimes take the place of the old Oak or Chestnut. One advantage of such work is that it looks well on the walls even before we get our plants up, and there is the great facility of being able to tie where we wish, thus avoiding the use of nails and the other miseries of training against walls.

We have used Bamboos in forming trellises away from walls with very good results, and now propose to make trial on a fruit wall of a trellis-work of slender Bamboos put together in 2-yard lengths or so, under cover in winter, and when complete carried out and attached to the wall by strong eyes. The particular size of trellis used on walls depends on the trees we have to train; for training Peaches and Nectarines one must have rather a smaller size in the spaces of the trellis-work than we have for the training of Pears. Trellis-work made of Oak or Chestnut lasted for many years, and was thoroughly efficient, and a well-made trellis of this sort saves us all the trouble and injury to the wall of pock-marking it with nail holes, forming nests for vermin that destroy the trees or their fruit.

There remains the question of fixing our trellis-work of Oak, Chestnut, Pine or Bamboo. In old walls, holdfasts must be driven; in new ones, pieces of iron with strong eyes should be laid along here and there in the courses of brick or stone as the work goes on. In a wall we are building now we use one with a forked end, so that, set in mortar, it cannot move. These

strong eyes are set one at about every 3 feet of wall surface.

Where the wall surface is given up to the training of Pears, Cherries, or other trees that require a stronger tie, it is best, we think, to use stout galvanised-iron nails not less than 5 inches long and at about a foot apart. To these we can tie anything securely, and if for the training of very young shoots we wish to tie to a stick, it is very easy to do this by fixing a stick from one eye to another.—*Fidd.*

NOTES AND QUESTIONS.—FRUIT.

Apple Albury Park Nonsuch.—With me this fruited for the first time this season. The fruit is very pretty, somewhat conical in shape, pale green on the shaded side, flushed with red on that fully exposed. When cooked it has a pleasant flavour.—B. P. S.

Apple Wealthy.—The fruit of this is rather above the medium size, handsome both in shape and colour. The tree is a free grower and good cropper, but, like many others of its class, it does not keep sound for any length of time, but while in season it is of first-class quality.—S.

Apple Chelmsford Wonder.—The fruit is much after the stamp of King of Pippins, but larger and not so highly coloured. The tree has a somewhat loose habit, foliage large and stiff, similar to that of Blenheim Orange. It is a most prolific bearer, and the fruit keeps well.—P. B. P.

Apple Beauty of Bath.—With me the tree is a vigorous grower, and though it is said to be a prolific bearer, the reverse is the case here, for though the trees are several years old they have never produced anything like a crop. The fruit is very handsome and of good flavour.—P. Sussex.

Apple McIndoe's Russet.—Though the tree is hardy and a free bearer with me, this variety is disappointing, the fruit being rather small and of poor quality. This season it is almost worthless. The tree, however, is robust and does not canker, so that when it attains a larger size we may hope for better results.—H. C. P.

Apple Hambling's Seedling.—This new Apple was sent out in 1894. I like the appearance of the fruit, which is pale green, the surface dotted over with small greyish specks. It looks likely to be a long keeper, but this and its cropping capabilities I have yet to put to the test. The tree I have is a low bush and the variety evidently has a good constitution, as is shown by the fine clean growth made this season.—A. W.

Peach Bellegarde.—I am sorry to read that "H. R." is unable to get this valuable late Peach to colour properly with him. I have it growing on a west wall, where the fruits not only attain to a large size, but colour to perfection; in fact, during the last and the previous seasons the colour was quite a blackish red. It is a fine late sort, the fruits large and highly flavoured, and being such a good cropper, it should be grown wherever the Peach will succeed outdoors.—A. W.

Apple Sandringham.—The tree is of good habit and does not canker here like so many other varieties. The fruit is large and handsome when ripe, being yellow on the shaded side, while that fully exposed to the sun is bright red. We have but few Apples of this class that keep sound so late in the season. Unfortunately most of the large kinds are soft and soon lose their flavour, but in this we have one of first-rate quality that remains in good condition till March.—H. C. P.

Apple Newton Wonder.—In this we have not only one of the handsomest shaped Apples in cultivation, but at the same time most prolific, for this season when so many failed to produce a crop, trees of it were heavily laden with fruit. It is of free habit, and does not canker on a cold, heavy soil, which is a great point in its favour. Not only is the fruit of good shape and fair size, but solid, and keeps well, and from what I can judge of its qualities Newton Wonder has a great future before it.—P. U.

Apple Bramley's Seedling.—The tree is an extra strong grower on our heavy soil, but does not canker. It is, however, one of the shyest varieties I have. This is the first season that my trees have produced any fruit, though they have been planted several years, and now there is not more than a third of a crop. The fruit, however, is large and sound, and to all appearance will keep well, but unless the

trees fruit more freely they will not pay for the ground they occupy, so must be discarded.—H. C. PRINSEP. *Buried Park, Uckfield.*

Apple Rambour Papelon.—This Apple, which is quite new to me, I saw growing in the Royal Horticultural Society's Gardens at Chiswick a few weeks ago. The tree, which is a bush, was carrying a few fine fruits, which were quite distinct and handsome in appearance. I have seen it stated that it is a long-keeping sort, and should imagine it to be so, judging by the firm, clean-looking appearance of the fruit. If such is the case and it proves to be a good bearer, it will be a valuable addition to our late-keeping Apples.—A. W.

Pear Beurre Alexander Lucas.—This is a very handsome November Pear and one which gives off a powerful aroma, reminding one very much of Mme. Troye in this respect. All further comparison must, however, here cease, as the variety just mentioned is a crisp eating rose-water-flavoured Pear, while B. Alexander Lucas has a melting flesh, with a delicious flavour. It succeeds very well as a cordon on the Quince. The tree makes excellent growth and seems to be quite hardy. Intending planters of wall Pear trees should include one or two trees of this sort.—S. E. P.

Apple Belle de Pontoise.—This is a rather new Apple and withal a very handsome one, both in outline and general appearance. Its shape it is somewhat between Blenheim Orange and Bismarck, and when well grown is beautifully coloured. I noticed a grand dish of it at the recent fruit show held at Hereford. As a bush tree it grows vigorously, and will no doubt when established bear well, but so far I have not been able to form a correct estimate of its cropping powers. As regards its appearance, there is no question about its being a fine handsome Apple, and if it will only crop freely it will no doubt in time be grown in quantity for market.—A. W.

GARDEN FLORA.

PLATE 1198. INCARVILLEAS.

(WITH A COLOURED PLATE OF I. DELAVAYI.*)

THE genus *Incarvillea* is peculiar to Central Asia, and is closely allied to *Amphicome*, of which *A. Emodi* and *A. arguta* are in cultivation in greenhouses. It belongs to the order Bignoniaceae. Until about five years ago only two species were known, viz., *I. chinensis* and *I. Olge*, of which *I. Koopmanni* is a variety. Now there are said to be ten, and of these we have in cultivation the following:—

INCARVILLEA DELAVAYI.—We owe the introduction of this beautiful plant to the French missionary, the Abbé Delavay, who discovered it on a lofty mountain in Yunnan, West China, at an elevation of 8000 feet to 11,000 feet. Seeds of it were obtained and distributed by Messrs. Vilmorin and Co., of Paris, in 1893, and also by Mr. W. Thomson, of Ipswich, who first offered it under the name of *I. alpina*. It was first tried under cool greenhouse treatment, but experiment proved that in sheltered gardens—at any rate, in the warmer parts of the kingdom—it was hardy, and far more satisfactory in the open air than when grown under glass. It first flowered in a cool greenhouse at Kew in May, 1895, and in the same month Sir Trevor Lawrence showed a plant of it at the Temple show, where it obtained a first-class certificate. Mr. Barbidge also records in THE GARDEN, June 8, 1895 (p. 394), the flowering of a plant by Mr. T. Smith, of Newry, in whose garden some plants had passed through the winter uninjured and were then pushing up their leaves and flower-spikes. Since then the plant has been generally cultivated, and it is now recognised as a first-class summer-flowering plant for a sheltered border or nook in the rock garden. It has a stout, fleshy root-stock, with a very short subterranean stem, from which spring the deciduous fleshy,

* Drawn for THE GARDEN in Messrs. Wallace's nursery at Colchester by H. G. Moon. Lithographed and printed by J. L. Goffart.

bright green, pinnate leaves, each a foot or more long, the toothed leaflets 4 inches to 5 inches long. The flower-scape varies from a foot to 2 feet, or even more in length, and bears from two to a dozen or more flowers, which have a bell-shaped, lobed, green calyx an inch long and a trumpet-shaped corolla 2 inches long and 2 inches wide, coloured rich rose, with a few purple streaks and a tinge of yellow in the throat. If grown in pots, the plants should be rested in a cold frame in winter and allowed to start in spring in the same place. During the summer they should be stood in the open air, with the pots plunged in ashes. They prefer a rich loamy soil.

I. GRANDIFLORA.—A recent introduction from China, which flowered at Kew in June this year. It is similar to *I. Delavayi* in general characters, differing in its shorter leaves, more rounded leaflets, short scapes, bearing only one or two flowers as large as those of *I. Delavayi*, but with narrower calyx lobes and longer corolla lobes, whilst the colour is a deep rose-red. This may be only a form of *I. compacta*, discovered some years ago in Kansuh. Dried specimens show about a dozen scapes on a plant. Another species found recently in China and, I am informed, now in cultivation in France is

I. LUTEA, which is described as having yellow flowers as large as those of *I. Delavayi*.

I. OLIGÆ is hardy in a border against a wall at Kew, where its stems interlace and cover the ground for a yard square or so with its bright green pinnate leaves and, borne upon the upright ends of the branches, panicles of rose-pink tubular flowers each an inch long and wide. It was introduced from Turkestan in 1880, and a form of it, *I. Koopmanni*, was figured in the *Botanical Magazine*, t. 6593 (1881).

I. SINENSIS is similar in habit to *I. Oligæ*, but the flowers are bright red and shorter in stalk.

All these plants are certainly perennials and not annuals, as stated in botanical works.

W. W.

THE WEEK'S WORK.

HARDY FRUIT.

PEACHES AND NECTARINES ON OUTSIDE WALLS.—**AUTUMN PRUNING.**—Those who perforce of circumstances may have left the wood rather more thickly than they would desire will do well to give the trees a thorough overhauling now. Where any strong shoots must be removed, it is far better to do this in the late autumn than in the early spring. By so doing the wounds have a better chance of healing over than they would otherwise do, with fewer possibilities of canker or gumming in the future. Where the growth is at all strong, a corresponding check at the roots is most desirable, this being done at the same time. It may not be actually necessary to lift every tree, but if that be the case, do not hesitate in doing it, and if there is a tendency for the roots to strike downwards, place three or four roofing-slates under the base of the stem. This will be found effectual. Young trees have a disposition to grow too strong, especially if they are planted in a soil containing too much humus, and if it has not been possible to secure a heavy crop or two so as to modify their condition in this respect. These, too, will probably want room for extension, which also should receive attention, as before alluded to. Where the trees do not require to be lifted, it will be well for them, if they are making wood that is too strong to be fruitful, to cut around each one at about 3 feet or 4 feet from the stems and to a depth to reach the lowest roots. Then, after these have been carefully pruned, replace the soil in a firm manner, not forgetting that most essential work in every instance of lifting or replanting, viz., a thorough watering. As my trees are unfortunately upon walls with galvanised wire running horizontally, they have to be removed from the wires every autumn. When this is being done, the pruning, too, receives attention. At the present time all of this work is

finished, the weather having been most favourable for its performance. Now the only remaining operation is that of a good winter dressing of an insecticide. It might perhaps be as well to mention the naming of these and other fruit trees at this juncture. If dependence be placed too long upon the nursery labels the writing will be obliterated and perhaps a confusion afterwards arise. The Acme labels appear to serve a good purpose. I find them answer very well both inside and out. In any case use material that will be of a durable character.

WINTER DRESSING OF FRUIT TREES.—No better opportunity than the present can be had for giving this necessary and labour-saving work in the future thorough attention. Where there is the slightest need of such, do not by any means be induced to postpone it until the spring, but set about it with a determination, if not to completely exterminate, at least to so reduce the numbers as to minimise the injury they may do if after-attention be paid to them. With so many good and reliable insecticides as we now possess it might appear somewhat invidious to name any in particular. Mention will only be made of the following which I know by actual experience to be effectual. One of the oldest is Gishurst compound, which still keeps up its reputation. As a wash or for application with a brush, as in the case of American blight, it is one of the safest and best to use. The prescribed strength may in bad cases be exceeded. A more recently introduced insecticide is the XL All. This has great penetrating power, being most effectual and safe in its use. For the worst of cases, where insects habitually have given trouble, this remedy is advised with every confidence. Bentley's preparations, viz., soluble paraffin oil and insecticide, are both efficacious and reliable. The former has great penetrating and lasting properties, two strong points in combination. For use upon old walls or upon the rough bark, as that of old trees, it is, I think, the best of any to use. The latter is, so far as I have used it, a very strong solution, being well suited to desperate cases. When using any of the foregoing, never exceed the prescribed strength, save in the case of Gishurst compound, as instanced. The best time for applying these or any other insecticides as winter dressings is when the bark of the trees is well moistened, but not when it is actually raining. In dealing with American blight, two or three applications may be necessary, but when this operation is done, let it be in a thoroughly efficient manner. No half measures will suffice to exterminate it. I have now some Apple trees which are attacked, but upon which extermination has been pronounced, and Gishurst will be put to the test to accomplish it. In doing this, the top soil will be removed to see if the roots are at all affected. Cherry trees are frequently infested, as most of us know to our cost, with the black aphid. The past summer was in some instances a notable one in this respect. Fortunately, however, a strong application of XL All was applied in the winter previous, and then during the summer it was a comparatively easy matter to keep this insect pest in abeyance by the use of Bentley's quassia extract. It cherries now receive two doses at short intervals and another in the spring, both labour and annoyance will be spared next season. Possibly some few shreds of the old type—viz., cloth and leather—are still in use. If so, they should all be removed if insect extermination is aimed at. The best shreds by far are the medicated ones; in these the insects do not find a congenial home.

PEARS AND PLUMS against walls I have noted during the past season or two as being troubled with a small caterpillar to a rather serious extent. If others have observed this, the application of a winter dressing is most desirable. So also is it in the case of the Plum or blue aphid both against walls and upon standard trees. If immediate attention can be given to pruning, it will be more expedient to do it, also the nailing, using all new shreds, and then to apply these winter dressings

both at right angles with the walls and also obliquely.

PLANTING.—As the weather still remains open and favourable for this work with the ground in good condition too, planting should be pushed forward without delay. Note previous writings and cautions against a too free use of nitrogenous manures, which, good as they are in their way, are not the thing for young fruit trees fresh from the nursery. Their use in the nursery up to the removal stage has no application whatever when transplanted to our gardens. So far it has been important to secure a free growth to lay the foundation of a future thriving tree. Continue the use of nitrogenous manures, and this free growth will increase out of all proportion and end in, first, unfruitfulness; secondly, in severe pruning of the branches, if not root-pruned; and, lastly, in canker, or in an ill-proportioned tree. This is a short, but fair summary of what has often occurred. It need not be so, however, with due caution and frequently, too, with less expense. Even loam of moderate quality is much better than farmyard or other exciting manures. The first object is (or should be) to establish a tree without fostering a rank growth, and then to keep it in submission by cropping afterwards. If pushed for time the mulching of newly-planted trees may be deferred for a few weeks, but do not let it escape notice later on. This mulch may be of any manure at hand, either from spent Mushroom beds or the stable or farmyard. Possibly before it is applied the trees may need a gentle, but firm treading, with a little more soil added upon the surface to bring it up to the regular level. **HORTUS.**

KITCHEN GARDEN.

EARLY PEAS UNDER GLASS.—Of late years we have had more choice of varieties for growing in the way described, and, what is better, there is superior quality in these early varieties. This is a gain in the right direction, as the small white-seeded Peas when forced are of short duration and not of the best quality. For pot culture, Sutton's May Queen is a beautiful Pea on account of its quality and the freedom of growth. The haulm branches close to the soil and the pods hang in profusion. The height of the plants, if not too crowded, is only 2 feet. It is one of the earliest kinds I have grown. Another very fine forcing Pea is Early Giant, and I know of none to equal it for cropping. It is rather tall for frames, but for quantity of crop and quality it is excellent. For starting under glass at this season and then planting out, I do not know of any kind better than Springtide, a very dwarf variety and one of the first to mature. Anyone who can afford space to grow Peas under glass will do well to give this a trial. Another equally good kind is Daisy. This I grow in quantity for planting out. Many sow in small pots and later on transfer to larger ones, but I find I lose time, as in too large pots the roots decay. I find it best to fill the pots in which the Peas are to grow about three parts full, and then top-dress as growth is made. Avoid crowding the plants. If sown thickly there should be severe thinning when the plants are well above the soil and it can be seen which is the strongest. High temperatures should be avoided, and as growth increases, a position near the glass and plenty of air are essential. Peas do well in frames, as grown thus they are close to the glass. In pots more warmth may be given to start the seed, and in all cases use fresh seed. The soil should not be too heavy. I find loam, spent Mushroom manure, and some bone-meal suit the pot plants.

PEAS FOR OPEN GROUND.—Many growers who need early Peas sow for first supplies in the open ground during this month if the weather is open. If Peas are sown in the autumn it is better to sow whilst the soil is in fair condition as regards moisture than to defer it to mid-December, as at this date the seed often fails to germinate. With open-air sowings there must be more care in the selection of varieties. I have found such kinds as Chelsea Gem, Wm. Hurst, and Sutton's and

Carter's Forcing do well in well-drained soil. These being very dwarf are most suitable for the purpose. In wet or clayey soil I do not advise sowing these varieties now, as the seeds fail to germinate freely. In well-drained land there need be no fear of the seeds germinating. Even then the grower will have difficulties; birds and mice are very fond of the young growths, and must be watched. It may be asked if it is worth while to sow Peas in November. I do not advise it only under the most favourable circumstances. In the open ground it will be well to sow thickly at this time of year. Another mode of culture that may be adopted with advantage is sowing in pots for planting out. I do this largely, and get an excellent return, as by giving the plants a start under glass one can grow kinds with a marrow flavour and which give larger pods. I sow in cold frames at this date in 5-inch pots, six to nine seeds in a pot, and place close to the glass. By the end of February they are strong plants, and having been grown as cool as possible can be planted out without fear of losses and soon take to the soil. During the winter and at sowing time they need but little moisture, and I find the plants rarely go back if not given heat from the start. For sowing in this way, such kinds as Springtide, May Queen, and Daisy are the best.

FRENCH BEANS.—When we are able to gather French Beans in the open in the middle of November, the plants having had but slight protection, it shows what a remarkable autumn we have had. It will now be advisable to give more warmth to the plants in frames, as after this date it will be out of the question to get a free set, as the plants do not make new growth freely. Every endeavour should be made to assist the pods to get those that are set to swell freely. To do this, water with tepid manure water and give a little more warmth in the pipes, at the same time giving more air. The pods should be gathered regularly, as if fully grown they will prevent the smaller ones swelling. I do not advise, as is often done, sowing in pots at this date for supplies early in the year. If necessary it must be done, but the crop is so poor in comparison to the labour and room occupied, that Beans sown in pots at this date are not worth growing. Far better sow early in the year, then with lengthening days and more sun-heat the crop will pay for room occupied. After that date seed may be sown every three weeks to keep up a regular supply.

LATE CELERY.—It will be advisable to now earth up the latest rows of this; indeed, in a heavy soil, many will have already done this. I never earth up the latest lot till the end of October, but this year I am much later, as it was not safe to do the work earlier, the soil being none too moist and the plants backward. Previous to earthing up it will be well to give a good dressing of soot, as the plants will now be liable to attacks of slugs and worms, and when in a blanched state later it is difficult to apply remedies. In land infested with slugs I find it well to place salt on each side of the plants in showery weather a few days in advance of moulting up. This, with a free dressing of soot, will scatter the enemy. It will not be well to tie up late plants too close, as with open weather the leaves will still continue to develop. Previous to earthing up it will be well to see if the soil at the roots is moistened, as though the rainfall of late has been plentiful, I note some of the earlier-lifted roots are quite dry at the base.

PLANTING LETTUCE.—Though full late to advise planting Lettuce, the mild season will admit of the work being done if the soil is light and well prepared for the plants. There is a great gain in having a good breadth of autumn-planted Lettuce, as, though there may be considerable losses in the winter, the crop is so much earlier. It often happens that Lettuces planted out will stand whilst those in the seed-bed are killed. Owing to the seed germinating rather badly, I planted much later than usual. I prefer October for the work, but the land is in capital condition, and I

am now planting on south sloping borders in front of vineries. Others may have a wall to spare, and at the foot of this the plants will do well. It is important to make each plant quite firm. I lift as carefully as possible with the roots intact, and in heavy soil the addition of lighter soil for the surface will be advantageous. Years ago I had a number of turf-pits. These I found invaluable for Lettuce, and others may be able to give temporary shelter in the way of boards or frames. Neding large quantities, I plant some thousands on borders and get a fair return if the plants are protected from birds and slugs.

SPRING CABBAGE.—Owing to the heat and drought at the time of planting the first lot, there were more losses than usual. These should have been made good, and it will now be well to prepare the plants for the winter. It is well to thoroughly firm each plant by treading along the rows each way, and then moulding up well to the lower leaves. This firming of the plant is a great safeguard, as the Cabbages make a sturdier growth and are thus better able to resist frost. I lose very few plants by running or other causes when planted in firm soil and the plants treated as advised. Later beds will need filling up where plants have failed. I have never had so many plants go blind as this season. I always after filling up the quarters prick out into lines 6 inches apart a goodly number of seedling plants for early spring use, these coming in useful as a succession to the earlier ones. Plants treated as advised may be made good use of. Pickling Cabbage, if required of a large size, should now be planted.

S. M.

STOVE AND GREENHOUSE.

ABUTILONS.

THESE, several of which will flower continuously throughout the year, do not command the attention they deserve. Some twenty years ago, Mr. J. George raised some fine varieties from *A. Darwini* and *A. venosum*, and they seemed likely to be popular, but have apparently dropped into the background since, for they are rarely exhibited at the present time, and I doubt if a good collection could now be found. At the time I refer to, the Royal Horticultural Society had a good collection, and they were grown both as pot plants for winter flowering and for bedding out in summer. For the latter purpose they were certainly very attractive, but for winter flowering they were not quite a success, as being within the range of the London fogs all the buds would drop after a day's visit of this destructive element. I have never had an opportunity of trying them beyond the reach of London fogs, but should think they would prove valuable, especially such varieties as *Golden Fleece*, which is of a deep golden-yellow with large flowers. The pure white *Boule de Neige* is also very free. There are numerous varieties with flowers varying from orange to deep crimson. In addition to those which are worthy of culture for their flowers, there are several with variegated foliage which are useful both inside and outdoors. One of the finest is *A. Sellowianum marmoratum*, with large, heart-shaped leaves, beautifully marbled with yellow and green. This is most suitable for indoor culture. *A. Thomsoni* is the best yellow variegated variety for outdoors, and *Souvenir de Bonn* is a good companion, having a silvery white margin to the leaves. The variety referred to in THE GARDEN (p. 400) is quite a distinct species. It is perhaps best known as *vexillarium*, but *megapotanicum* is the most correct name. The variegated variety is the most desirable. It may be used as a climber for the roof of a cool greenhouse, and is very effective. The

flowers, which have a peculiar globular, crimson calyx and yellow petals, are produced almost continuously throughout the year, and are seen to advantage when hanging from a roof. This variety may also be used for the flower garden. Grafted on tall seedlings of the *venosum* type they make pretty standards.

All the *Abutilons* like a good loamy compost and a liberal supply of manure. Provided they are kept free from red spider they give little trouble, but being of rapid growth, they soon get too large for ordinary use, but this may be overcome by propagating periodically. The cuttings will root freely in the ordinary stove propagating pit. The strong-growing tops if taken off about 3 inches long and inserted singly into 3-inch pots, taking care that they do not get withered, will soon root, and in a short time will be ready for potting on into larger pots. Cuttings put in now will make fine plants for planting out in the spring or for early flowering in the conservatory. If a little more attention were paid to keeping up a stock of young plants I think *Abutilons* would be more popular. I may add that they seed freely, and by judicious crossing some fine varieties may be obtained. It is a mistake to cross various colours indiscriminately. The best habited plants should be selected for the seed parents, and the pollen may be taken from a brighter shade of a similar colour. The pollen parent will generally improve the colour, while the seedlings will retain the habit of the seed-bearing plant. Seedlings generally run up rather tall before flowering, but as soon as they have been tested those worthy of perpetuating may have their tops taken off and rooted as recommended above, while some of the strongest of the inferior varieties will make good stocks for grafting *A. vexillarium* on. H.

Urceolina pendula.—This extremely pretty bulbous plant has been flowering for some time, and, being so distinct from anything else, it is sure to attract attention. The blossoms, in shape like inverted urns, are of a rich golden-yellow colour, except just at the mouth. The individual blooms last some time, and as they are borne during the autumn months, such a distinct and attractive plant is all the more appreciated. Beside the specific name of *pendula*, it is quite as frequently met with under that of *aurca*. It is a native of Peru, and was first discovered by Mr. Pearce when travelling for Messrs. Veitch, with whom it first flowered in 1864.—T.

Shading Lapageria.—This fine cool house climber dislikes hot sun, and must, therefore, get some shade when grown in a house which receives the full sun during the hottest part of the day. That shading may be carried to an excess I have, however, this year had good proof. I have a plant in a lean-to house which has hitherto annually produced hundreds of blooms. This season the amount of bloom produced has been far below the average, and I am convinced that this deficiency is caused by too much artificial shade. Hitherto I have either shaded with whitening or with mats, which have been removed when the sun began to lose power, but this year when the hot weather set in I nailed some old mats on the roof, and these remained all through the summer and early autumn. The plant has a very green, healthy appearance, but it is only where shoots escaped a little from the dense shade that flowers were freely produced. It was curious to note that one shoot which pushed through a hole in the glass was crowded with buds. It is evident, therefore, that in the case of *Lapagerias* shading may be overdone.—J. C. B.

Abutilon insigne.—This Brazilian species of *Abutilon* is widely removed from the ordinary garden varieties, and cannot be induced to flower in a satisfactory manner when small, as many of them will. Despite this, it is, however, in every

way a striking and beautiful kind, which is seen at its best as a roof or pillar plant, or at all events where so situated that it has good space for its development. It is a strong-growing species, with large heart-shaped leaves of a particularly thick rugose character. The flowers are, as in most of the other *Abutilons*, drooping, and borne on long slender stalks. The shape of the blossoms is that of an open bell, the colour being a deep crimson with blackish veins, and the peduncles being so long an extremely pretty effect is produced when the plant is in full flower. It blooms for a considerable time, but, as a rule, the greatest quantity of blossoms is borne during the autumn months. To succeed with *A. insigne* it needs more heat than the garden forms, and should be given the warmest part of the greenhouse, or, better still, an intermediate temperature. Being of free, vigorous growth, it is more satisfactory planted out in a border than when confined in pots.—H. P.

Bouvardia odorata alba.—This variety of *Bouvardia*, alluded to on page 366, is quite distinct from any of the numerous forms in cultivation, and it is in every way a very desirable kind. The habit is good and it flowers freely, added to which the flattened clusters of blossoms as well as the individual flowers are large. As pointed out on page 366, the comparatively short tube of this variety is greatly in its favour, for it is not so liable to break as the long-tubed section, of which *B. Humboldtii corymbiflora* is a well-known example. Another large flower with a short tube is the pure white variety *Purity*, first sent out by Mr. H. B. May, of Edmonton, now some years since. Though bearing the name of *B. odorata alba*, the flowers are really not pure white, being slightly tinged with pink, and in the bud state this hue is still more pronounced. It is of continental origin, and when sent out it was described as a hybrid form of *B. Humboldtii corymbiflora*. At all events it is a charming variety, and should, where these plants are grown, be always included in the collection.—T.

VIOLETS IN POTS.

ALTHOUGH it has its advantages, the pot culture of Violets does not, as a rule, find favour among gardeners. Some years ago gardens about Chislehurst, in Kent, were noted for their splendid Violets, the plants for the most part being flowered in pots plunged in ashes in frames or shallow pits. Runners were planted out in May, a north border being given, leaf-mould being the principal ingredient added. The parent plant was kept to a single crown, some half-dozen runners being allowed to form on each, these being duly pegged into the soil at equal distances. In October lifting and potting were done, but of course no soil to speak of could be got to the roots, a fact which set me against this system of potting, as the frames had to be kept close and the plants syringed until they became established. Ten-inch pots, well drained and filled with light loam and leaf-mould, were used, Violet growers in those days not tolerating manure. The parent plant was placed in the centre of the pot, the strong-rooted runners being equally disposed around, plunging to the rim completing the operation. The Chislehurst growers grew only the Neapolitan, Marie Louise being then little known, and they may have found the pot system suit this particular variety best. Potting up a few scores of plants in autumn, one plant in each pot, is a good plan where a position near the glass in a cool, airy house can be given, as it enables one to gather a few bunches in time of severe frost without uncovering the frames. Good plants carefully lifted with a ball of soil will take an 8-inch pot, any fairly rich loamy compost answering for potting. Give ample drainage, and when potting leave a good margin for water. It will be best to keep the plants in a frame till frost necessitates their removal to the house. Syringe overhead lightly on fine days to freshen the foliage and lessen the liability to red spider, and take care never to let the roots suffer from

want of water. Some of the best Violet pits I have seen are at Thoresby. They are furnished with a flow and return hot-water pipe, which is warmed in very sharp weather. The annoyance of being unable to open the lights for weeks together, as is sometimes the case in unheated pits, is thus avoided. J. C.

BEGONIA MOONLIGHT.

I HAVE not seen this *Begonia* for some time, though twenty years or so ago I used to grow it in considerable numbers. It was first brought under my notice by the beautiful flowering specimens in the Royal Horticultural Society's gardens at Chiswick, which created such a favourable impression that it was then much sought after. To obtain good flowering specimens it was necessary to propagate it on the same lines as those laid down a few weeks ago in *THE GARDEN* for the increase of that extremely popular variety *Gloire de Lorraine*, for, like that kind, cuttings of the flowering shoots would never break out and form a bushy specimen. Such being the case, the plant was partially rested and cut back, when the shoots pushed out near the base were taken off and treated as cuttings, and, like *Gloire de Lorraine* above noted, they formed pretty bushy specimens.—H. P.

—Like "H." I have not seen this variety for some time, having lost the stock of it some few years back. It is, however, a remarkably free-flowering kind, and, as "H." justly remarks, would make a fine companion to *Gloire de Lorraine*. Another free-blooming sort is *B. Carrieri*. This may be had in flower at any season, but by striking a batch of cuttings late in the summer and growing the young plants on quickly afterwards, they will bloom during November and December. With respect to this variety, I have two types of it, the one having a smooth leaf, that of the other being hirsute, but they are identical in the form and size of flower, and both are very free flowering. *Gloire de Seaux* is another free-flowering sort, but later, and this has ornamental foliage, the colour of the leaves being a bronzy red. *Gloire de Lorraine* is, however, the freest flowering of all. At the Malvern Chrysanthemum and fruit show, two splendid groups of this variety were staged by Mr. Crump, of Madresfield Court, and Mr. Fielder, of St. James's, West Malvern, which attracted attention. They were certainly the best grown examples of this variety that have ever come under my notice.—A. W.

HYDRANGEAS FOR HOUSE DECORATION.

AT one time large specimen *Hydrangeas* were grown for placing in front halls and other conspicuous places in private mansions, and no plant is better adapted for it. Market growers have a knack of producing one immense head of bloom on small single-stemmed plants, and while these may have their own special merit, I prefer larger plants with numbers of trusses evenly disposed over a surface of dense green foliage. It is then its real value as a decorative plant is seen. It takes several years to produce large specimens, but they well repay the labour and patience. Well-drained pots and a good holding yellow loam, three parts, and one part well-rotted manure and road grit suit them well. It is always wise to give cold house or pit protection in spring, as sharp frost is apt to catch the young growths and turn them black; but all danger of frost being over, the most suitable position is a semi-shaded one out of doors. Towards autumn, however, a sunny position is necessary for thoroughly maturing the growths. The plants must be assisted with liberal doses of liquid manure, and the flowering stems supported with neat sticks; if these are painted green, so much the better. After flowering, the old growths should be cut out, and the new ones from the base of the plants encouraged. When at rest during winter they are best plunged either in ashes or leaf mould in a sheltered place. Large

plants may be supported in the same pots for several years by liberal top-dressings and frequent supplies of liquid manure, and when too ungainly to be retained as pot plants, they may be planted out in sandy soil in pleasure-ground borders, younger specimens being brought on to replace them. J. C.

ZONAL PELARGONIUM GUILLOM MANGILLI.

I SHOULD be almost inclined to go a little further than the writer of the note in praise of *Guillon Mangilli*, and to say that if restricted to one variety this would be my selection, for so far as pot work is concerned alike for summer and winter flowering nothing could be better either in habit or freedom of bloom. It possesses the merit of growing vigorously and yet without coarseness; in fact, there is the same difference between this and many other varieties grown in pots as between a very short and a long jointed Vine. I want a fair amount of zonals in pots to stand in different positions outside during the summer months, and having decided to rely on a less number of large plants rather than a lot of smaller ones, picked out early in the spring a selection from those that had done duty in 5-inch pots through the winter months, headed back the ragged growth a little, and placed two of each variety into a 14-inch pot, potting firmly in the best loam at my disposal (which, by the way, is rather on the sandy side), the only other material being a couple of inches of dry cow manure over the few crocks used. I find this cow manure a great help; it has become thoroughly saturated by the time the roots find their way down and acts as a rare stimulant. Liquid cow manure is also the best stimulant to use during hot, dry weather when the plants are in full vigour and flowering well. The sorts used were *Raspail*, *Guillon Mangilli*, and *Mme. Charotte* among the doubles, *Niagara*, *Duchess of Marlborough*, *Lord Aberdeen*, *Majestic*, and *Lady Carlisle* in the round-flowered singles, with *Mrs. Hayes*, *Aurore Boreale*, and *Gloire Lyonnaise* in the big nosegay section. The plants were staked enough to draw them over the pots, at the same time avoiding any formality, and all did well, the largest of them being at the end of the season quite 3 feet high and as much in diameter, but, as I have said, *Guillon Mangilli* was an easy first. They have found a home in the *Camellia* house for the winter months, and most of them are still in flower.—E. BURRILL.

—The note concerning this double-flowered *Pelargonium* on p. 390 shows well that a good variety will hold its own for years, though swarms of so-called improvements may be put into circulation during that time. I was very pleased to read the article in question, the whole of which I fully agree with. My first plant of it was obtained from the Continent as long ago as 1875, this being, I think, the year in which it was sent out.—H. P.

Hæmanthus natalensis.—I have *Hæmanthus natalensis* and *H. tigrinus* dry after a good growth and just now starting. Should they be kept dry or watered? House rather cold.—T. NISBET.

* * * The two species of *Hæmanthus* above referred to should be kept moderately moist in order to perfect their growth, as the dormant period is now past, and they will continue to grow throughout the winter and spring months, after which they go to rest. At the same time, as the house is rather cold particular care must be taken not to over-water them, though, of course, they will need more when in full growth than when just starting.—Ep.

Nerine elegans alba.—It is now five years since a first-class certificate was awarded by the Royal Horticultural Society to this *Nerine*, which is, as far as I know, the only really white-flowered kind of all the numerous forms in cultivation. A specimen now in full bloom has a flower-scape about 18 inches high, the head of blossom being just over 6 inches across, and consisting of seven-

teen flowers, each 2 inches or so in diameter. The six segments are not disposed in a regular manner, being arranged equidistant from each other on the upper half, thus giving the appearance of a lip being wanting. The segments, which are about one-third of an inch wide and more or less undulated, are pure white, though in the bud state the flowers are slightly tinged with green. The leaves are from a foot to 18 inches long and about three-quarters of an inch in width. They have none of the glaucescent character common to *N. curvifolia* (Pothergilli), but are of a uniform rich bright green tint.—H. P.

Hoya carnosa.—In case anyone is inclined to try the experiment of exposing this plant to frost, as described by "L. P.," I should like to say that I had a fine specimen killed by the breaking down of a boiler a few years since, though the frost was certainly not sufficient to freeze the compost hard as described on p. 390. I should think, too, in perning this note your correspondent had in mind plants that had filled their allotted space and were not required to grow any further. As for a plant that was old enough to flower fifteen years ago being still in a 9-inch pot, it is on the face of it obvious that it has not been "well grown"—that is to say, it has not been cultivated—or otherwise the roots would certainly require more space. The fact of the plant flowering annually does not prove it to be well grown, and I cannot understand why, even if the space is restricted, the plant is kept in so small a receptacle. Had I a similar plant to deal with, I should give it more room at the roots and cut away some of the older wood, as flower-spikes fifteen years old—and by the same token foliage of the same age—are not by any means as pretty or bright as those produced by young wood which would be laid in to fill up the place of old. I quite agree with "L. P." that it is often seen in a flowerless state through being too much excited, but it is not necessary to go to exactly opposite conditions and bring it to a state of semi-starvation.

FLOWER GARDEN.

JULY FLOWERS AT EXETER.

July and August, as a rule, are dull months with regard to most hardy flowers. The early things are over and the late flowers have not yet commenced to bloom. Doubly welcome, therefore, are flowers that bridge over the gap and look bright and cheerful during the months mentioned. In the well-known nurseries of Messrs. R. Veitch and Son, Exeter, there is a border devoted to alpines and all kinds of choice hardy plants, and I will here mention a few of the most important varieties which bloomed in July and August. *Senecio Greyi* (see illustration) when photographed was a mass of golden-yellow flowers. So far the plant has stood two winters without protection, and it forms at present a neat little bush about 18 inches through. The flowers are each about the size of a shilling, with golden-yellow ray florets and a central disc of darker yellow; they have an involucre of woolly bracts, and are arranged in large corymbs. The leaves, which are densely crowded and very thick and leathery, are thickly covered with a grey pubescence, reminding one of *Eleagnus*. *Oenothera rosea* is very ornamental when covering the border with long prostrate shoots decked with bright rose-coloured flowers quite the size of a five shilling-piece. It does not seem to mind the heavy soil nor the sunny exposed position in which it is flourishing. *Convolvulus altheoides* is a gem, flowering profusely, and in its season is literally covered with bright rosy pink flowers fully 2 inches across. The leaves are covered

with minute silvery hairs, giving a somewhat glaucous hue to the whole plant. To be seen at its best *Convolvulus altheoides* requires support. Rambling as it pleases over a few branches or Pea sticks it makes a charming and graceful ornament, and will grow in any border. *Sisyrinchium striatum* has bright primrose-yellow flowers, which gradually change to a deep golden yellow towards the centre, with a small black spot towards the base of each petal. The flowers are veined with dark brown at the back and appear in whorls. The flower-spikes are 2 feet in height. The leaves resemble those of the German Iris in size and shape, but are less rigid. The plant spreads rather rapidly in moist ground, and must therefore not be planted close to smaller plants, which it would destroy. *Asclepias fascicularis* is a robust perennial 2½ feet to 3 feet high. The leaves are opposite and conspicuous for their size, being about 5 inches to 6 inches long and 3 inches to 4 inches wide. They have a very distinct mid-

Senecio Greyi. From a photograph sent by Mr. F. W. Meyer, Exeter.

rib, and are somewhat downy at the back, with entire margins. From the axils of the upper leaves spring umbels of numerous fragrant flowers on pedicels each 1½ inches in length. The flowers are small and have pink petals folded in a peculiar manner. The calyces appear completely inverted, and, having green sepals striped with purple, give the flower a somewhat inconspicuous appearance. *Linnaria Cavanillesi*, with its Thyme-like foliage and its neat spreading habit, has flowered all the summer, and is certainly a most attractive plant where it can spread over stones and show its pretty purplish blue flowers with their deep yellow throat. *Linum salsaloides* somewhat resembles *Linum monogynum*, but the petals are rounder in shape and more reflexed. On closer examination it will also be found that the flowers are not pure white, but striped with minute purple veins, which are specially noticeable at the back. The foliage, too, is more

Heath-like, and resembles that of *Linum alpinum*. It is an elegant little bush 18 inches high and 2 feet in diameter. Why is not *Dianthus Atkinsoni* more extensively grown? The large flowers this year have excelled themselves—perhaps owing to the brilliant sunshine—both in size and colour. A deeper or more brilliant blood-red-carmine colour cannot be imagined, and as it is now fairly plentiful, this gem should be grown in every garden. *Silene maritima rosea*, a charming rock plant, flowering in July, is 4 inches to 6 inches high, and has blush-white petals diffused with delicate pink, and veined with purplish rose, especially on the reverse side, the inflated calyx veined with purple. *Dianthus versicolor* forms here a little bush 12 inches high and 20 inches through. The flowers, which are very numerous, are deeply fringed and of a bright rose colour, covered almost completely with dark crimson spots. Towards the base of each petal the spots are larger and of a deep magenta colour, forming a complete ring. The calyx is dark purplish brown. It is altogether a delightful rock plant of easy culture. *Onosma stellulatum* resembles *O. tauricum*, but the flowers are of a paler sulphur colour. The leaves, too, differ, being shorter and broader and covered with stiff hairs, especially near the margin.

F. W. MEYER.

Elmside, Exeter.

Sowing Sweet Peas in autumn.

—Last year a correspondent expressed surprise at some Sweet Peas sown late in summer with a view to securing bloom in autumn, but failing to flower at that season, standing the winter and producing a lot of flowers in early summer. The winter was mild and the situation sheltered. Some time ago I was told by a florist that Sweet Peas if sown in autumn, at the same time and in the same way as the early dwarf cooking varieties, will stand the winter and bloom in May or June. I have never tried it, but believe they would if sown in a warm, sheltered position and light, well drained soil, and protected from cold, cutting winds in spring by means of small evergreen branches. Sweet Peas being such favourites where cut flowers are in demand, it would pay for the trouble involved even if this first batch were somewhat dwarfer and not quite so well flowered as those from spring sowings. Sparrows would have to be watched for at this season, as they will devour the flowering as well as the cooking Peas.—J. C.

Hollyhocks.—Hollyhocks are too much used for planting at the back of shrubby and hardy flower borders and not sufficiently for furnishing separate beds. Nothing, however, has a finer effect in autumn than a group of well-grown and flowered Hollyhocks of choice varieties in an isolated position on a well-kept lawn. They show themselves to the best advantage in a large round bed, stout green-painted stakes being used to keep each plant erect. The weakly Pea stick-like supports often seen are quite useless for tall, heavy specimens during high winds. Few now care to depend on named varieties, these being so liable to disease, but nothing finer can be wished than the fine strains now obtainable from seed. I think it is best to sow in a cold frame in early summer, transplanting when fit to some sheltered nook where, if needful, slight protection can be given in winter. Final transplanting can then be done the following spring and grand spikes secured in autumn. Hollyhocks are not the best

of things to lift; therefore plenty of room should be allowed at the first pricking out. Few things are grosser feeders; therefore give a rich larder, mulch in summer, and feed with liquid manure.—
NEWBURY.

LOBELIA FULGENS QUEEN VICTORIA FROM SEED.

I HAVE grown this Lobelia for many years, considering it one of the very best border plants. For many years I adopted the usual method of increasing the stock by division in autumn or spring with more or less satisfaction. I must confess, however, the results often were not so good as I wished. I observed as time went on the stock got weaker. When the plants bloomed early they formed a lot of seed-pods, although I never have been successful in ripening the seed. This I attribute to the want of heat at the ripening time. Some fifteen to twenty years ago I resolved to try raising young stock from seed. Accordingly I obtained a packet of seed. This I sowed in February in a pan, thoroughly soaking the soil before sowing the seed. The surface must be smooth and even, as the seed is very small. When sown, a light sprinkling of very fine soil or sand should be put over it and the pan placed in a close frame. When the plants are strong enough they are pricked off into boxes 3 inches to 4 inches deep in good holding soil or on a sheltered border, where they are allowed to remain till the following spring. If they have made good progress, they will be good strong plants by this time. I prefer the box system, as in this way the plants are easily managed when very small. In April I remove these to their blooming quarters, planting them thinly. I plant amongst them Tufted Pansies, dwarf white Antirrhinums, or something that comes into bloom early and covers the ground; this produces an effective bed over a long time. The plants are often allowed to winter in this position. When the beds are wanted the clumps are removed in the fall and replanted in a sheltered position in the kitchen garden. In the following spring these are divided and used as before. I sow seed every year or two to keep up the stock, and in this way I obtain the best results. When grown thus they often attain a height of 5 feet or 6 feet and bloom, as this year, well into the autumn.
JOHN CROOK.

Forde Abbey.

CARPET PLANTS FOR SHRUB BEDS.

OUTLYING beds in different situations in the pleasure grounds already partially filled with small specimen shrubs or coniferæ may receive at this season a carpet of some appropriate plant where portions of the soil are at present bare. Take Hollies, for instance. I have seen large beds filled with small specimens of the gold and silver forms, which were kept by careful annual pruning to a height and base diameter of about 4 feet, and although very nice in their way, it struck me the effect would have been much more pleasing if every other plant were removed and the spaces filled in with some nicely contrasting plant as *Chionodoxa sardensis*, *C. Tmolusi*, or some of the best of the *Muscari*. If a green carpet is considered advisable throughout the year, the bulbs could be planted sparingly and the space afterwards filled in with one of the green *Sedums*. If it is considered advisable to strengthen the stock of *Daffodils*, favourite varieties can be planted in the same way; indeed, all bulbs look well when associated with different forms of tree and shrub life. I think the wild forms never show to better advantage than in some dell in a wood that has been partly cleared of trees and undergrowth, and they seem to flourish exceedingly in

such situations, whether the growth is slight and the flowers quiet in their beauty, as in the Dog-tooth Violet and the Wood Anemone, or vigorous in foliage and massive and glowing in flower, as in the old double *Daffodil*. It is not, of course, necessary to confine oneself to bulbs or to very dwarf things for the purpose under consideration.

Among other plants that I have used with excellent results are *Pinks* and the dwarfier forms of *Geum*, *Linaria*, and *Potentilla*, and where beds are of large size, alternate patches of *Albino Pink* and *Geum coccineum* may be tried. The last-named should be in every collection of hardy plants; it stands a long time alike on the open border and in water. In using dwarf plants, especially in considerable numbers, preference should always be given to those things that are pleasing in flower as well as foliage. A mass of variegated grass, for instance, as *Dactylis glomerata*, is not to be compared to similar quantities of *Pinks* or *Linaria repens* *Snowflake*. If it is decided to utilise *Tufted Pansies*—and where they do well there are no better carpet plants—partially shaded and fairly moist situations, with rather a heavy soil, should be chosen, or, given seasons like that of 1898, they will present a pitiable appearance before the summer is over. I fear on light soils the stock is likely to run very short another season, for not only were hardly any cuttings available, but old plants are very weakly, and splitting up with any hope of success is hardly to be recommended until growth commences in spring.

E. BURRELL.

NOTES ON PEAS.

OF Peas I find none to beat *Duchess of Edinburgh*, the best Pea for cropping and flavour. It lasts longer in bearing and retains its flavour and sweetness longer than any other that ever I saw. I have grown it for about fourteen years. I grow *President Garfield*, *Satisfaction*, *Magnum Bonum*, *Perfection Marrowfat*, *Matchless*, *Maincrop*, and *Sutton's Royal Jubilee*, all good midseason kinds. Latest of All I sow about the middle of May for the latest crop.—J. AINEY, *Orton Hall, Tebay, Westmoreland*.

As early varieties I prefer *William I. Improved* and *Chelsea Gem*; midseason sorts, *Critic*, *Autocrat*, *Veitch's Perfection*, and *Duke of Albany*; late sorts, *Walker's Perpetual Bearer*, *Ne Plus Ultra* and a variety named *Downie's Amateur*. A row of 40 yards long sown on June 24, 1897, of the last variety kept up a good supply of Peas till the second week in November. The first week in June is quite late enough to sow the latest Peas, as a rule.—W. COMFORT, *Kylemore Castle, Co. Galway*.

I consider some of the old varieties as good as any. For early use I sow *William I.*; maincrop, *Telephone* and *Duke of Albany*; late, *Walker's Perpetual Bearer*, which I always sow in the latter end of May.—GEORGE CLARK, *Walcot Gardens, Lydbury North, Salop*.

I have found that *Early Giant*, *May Queen*, *Empress of India* and *William Hurst* are good early Peas, and *Stratagem*, *Sutton's Invincible*, *Maincrop*, *Satisfaction*, and *Magnum Bonum* good midseason varieties. *Autocrat*, *Veitch's Perfection* and *Ne Plus Ultra* are good late Peas of delicious flavour and heavy croppers. I sow the first week in June for autumn supply.—W. T. MOBSY, *Yate House, Gloucester*.

The best early Peas are *Chelsea Gem*, *William Hurst*; midseason, *May Queen*, *Duke of Albany*, *Magnum Bonum*, and *Improved Dr. Maclean*; late autumn, *Autocrat*, and *Veitch's Perfection*. I find the best time to sow for an autumn supply in this district is the second week in June.—E. SEMPER, *Scarby Hall, Scarby, Lincoln*.

May Queen is a grand first early Pea. *Defiance*, a second early, is a fine cropper and of grand quality. *Sharpe's Queen*, an old favourite, is truly a grand Pea. *Duke of Albany* still holds its own as the best main crop. Success appears to be a fine cropping Pea. The best early Pea I have grown is *May Queen*, beating the well-

known *American Wonder* by a week. Of midseason varieties, *Duke of Albany* and *Sharpe's Queen* stand head and shoulders above all others. *Veitch's Perfection* and *Sutton's Late Queen*, sown about the middle of May, and *May Queen*, sown from June 1 to 15, will keep up a supply to the end of October.—R. GREGOR, *Glenberry, N.B.*

The earliest and best with me is *Exonian*. It is a splendid cropper and of excellent quality. For second and general crop, *Senator* and *Veitch's Perfection* are both dwarf and good croppers and of good quality. Of tall varieties, *Dadd's Prolific* and *Goldfinder* are both excellent for crop and quality. For late crop I gather seed of the early varieties of the same season. Nothing succeeds better with me than *Veitch's First Early* sown the first or second week in July.—JOHN D. NANSFAWEN, *Whiteway, Chudleigh, Devon*.

The best early Peas which I grow and which I always find satisfactory, both in produce and flavour, are *Veitch's Chelsea Gem* and *William I.*; for second crop, *Daisy*, *Duke of Albany*, *Dr. Maclean*, and *Maclean's Best of All*. For late and autumn use I find the best are *British Queen* and *Ne Plus Ultra*. For autumn use the Peas are sown about the middle of June. If later here they get ruined with mildew.—F. FOAKES, *The Gardens, Twinn Minster House, Bradford*.

I do not grow a large number of varieties of Peas, but the undermentioned I find do very well on this light soil: *Exonian*, *Gradus*, *Supreme*, *Duke of Albany*, *Model*, *Telegraph*, *Danby Stratagem*, *Autocrat*, and *Ne Plus Ultra*, sown in the order given. I grow other sorts, but these I find give the best results. For early work on south borders I grow *Exonian*, which always does well and gives satisfaction at the table, being nice and green and of fair quality for an early Pea. At the same time in the open I sow *Gradus* and *Supreme*, which come in well after *Exonian*. For midseason I follow on with *Duke of Albany*, *Model*, *Telegraph*, *Danby Stratagem*, *Autocrat*, and *Ne Plus Ultra*. To give a good supply during late autumn I have had nothing to beat a good strain of *Ne Plus Ultra*. When plenty of room can be had, taking into account productiveness and good quality, I sow the last lot in trenches the first and second weeks in June.—H. FOLKE, *Gaddesden Place, Hemel Hempstead, Herts*.

For early use I prefer *Exonian*, *William I.*, *Veitch's Selected*, and *Chelsea Gem*; midseason and general crops, *Maclean's Wonderful*, *Veitch's Perfection*, *Advancer*, *Sharpe's Queen*, and *Dr. Maclean*, and late kinds, *Maclean's Best of All*, *Veitch's Chelsonian*, and *Ne Plus Ultra*. The last named, sown about May 31, I find by far the best for the latest crop. If severe frost does not come I can gather till the end of October.—J. RAINBOW, *Boughton Hall, Yorks*.

After a good many years of experience in trying a number of kinds of Peas, I have lately gone more in for *Ne Plus Ultra* as a main season Pea. I always raise a batch of early *William I.* under glass at the end of February. These I plant out about March 10. At the same time I sow a lot of *William I.* and *Ne Plus Ultra*, and when these are coming up I sow another lot of *Ne Plus Ultra*, and so on with *Ne Plus Ultra* till the beginning of June. The result of this is splendid Peas that have never been found fault with, and which continue to yield until the frost comes.—R. MCKELLAR, *Abney Hall, Chesham*.

I consider *William I.* still the best first early Pea. *Sutton's Ringleader* sown at the same time comes in a few days later, and is a useful first early variety. Bountiful sown at the same time is about a week or ten days later, and is a good cropping useful variety. I usually sow my first early Peas under glass about the middle of January and transplant in March. I sow out of doors about the middle of February. For midseason Peas I sow the first week in April and the first week in May. *Duke of Albany* is a useful Pea, and *Sutton's Peerless* and *Matchless Marrow Peas* are all excellent for midseason use. *Maincrop* is a good second early Pea. For late

crop the Ne Plus Ultra section are the best, including British Queen. Autocrat is a very fine late Pea of medium height. I never sow dwarf Peas, as I consider 3 feet 6 inches to 4 feet quite dwarf enough for a good crop of Peas. Autocrat and Ne Plus Ultra, or Reading Giant I always sow on June 18, and I never fail to get a good crop as late as Peas can be had in October and occasionally November.—R. MAHER, *Yattendon Court, Newbury.*

The varieties I grow for early supply and which have given general satisfaction are Extra Early for the first, and Chelsea Gem, Earliest Marrow, Early Giant, and Gladiator to follow on, with Veitch's Perfection, Duke of Albany, Exhibition Marrow, and Chelsonian, which I consider one of the very best Peas for flavour and cropping combined that has ever been sent out. I have given up growing Ne Plus Ultra, being convinced after repeated trials that Chelsonian is far the better. For late crops, Autocrat, Late Queen, Sturdy, and Dwarf Marrow if sown from June 1 to 20 will give a fair supply till late in the autumn.—J. BOWERMAN, *Hackwood Park, Basingstoke.*

My best Pea for earliest use out of many varieties tried is May Queen. Giant was excellent with splendid green pods and very sweet peas. Dr. Maclean is still my best to follow. Sown at the same time as Ne Plus Ultra, it comes in nice time to be over for the later variety to follow. Veitch's Perfection is of good constitution and always does well. Telephone is good, but I find Jubilee better, as it is not so tall, with splendid peas of nice marrow flavour. Satisfaction will become a standing variety, being a good cropper and with a fine constitution. Duke of Albany and Sutton's Giant are both good, followed by Ne Plus Ultra. Autocrat, and American Wonder sown the first week in July will keep up the supply till late in the autumn.—S. G. HULLER, *Chiffle Hall Gardens.*

Early Peas are not much grown. Of mid-season kinds, Carter's Stratagem, Veitch's Perfection, and Maclean's Best of All are what I usually grow. Sharpe's Queen and Walker's Perpetual Bearer do very well with me as late kinds. I consider the best time to sow Peas for an autumn supply to be from about June 15 to the first week in July.—T. CRAWFORD, *Bosahan, St. Martin's, Cornwall.*

The best Peas here for cropping and flavour are Autocrat, Ne Plus Ultra, Veitch's Perfection, Dr. Maclean and Exonian. The best early Pea here is Exonian; the best mid-season kinds, Ne Plus Ultra, Veitch's Perfection and Autocrat. The best kinds to yield a supply into the late autumn are Autocrat and Dr.

Maclean. As a rule I sow in succession from January to June 26.—A. BLACK, *Carton, Maynooth, Co. Kildare.*

Taking cropping and flavour into consideration, I find the Peas that do best here are Dr. Maclean, Hair's Dwarf Mammoth, Exonian, Abbot of Bardney, Stratagem, Veitch's Perfection, Duchess, Veitch's Maincrop and Autocrat. For a number of years I have grown Veitch's Selected Early Pea for first crop, generally sowing it in January or February as weather permits. Gradus makes a good succession, followed by

Vitis amurensis. (See p. 45.)

Dr. Maclean, Exonian, Abbot of Bardney and Hair's Mammoth. The best mid-season Peas here I find are Veitch's Perfection, Autocrat, Veitch's Maincrop and Duchess. I generally sow in the first fortnight of June for the last crop, the varieties used being British Queen, Autocrat and Ne Plus Ultra.—J. GEMMELL, *Ladykirk Gardens, Berwick, N.B.*

The best Pea for this garden I consider is Duke of Albany. It is prolific, handsome, and has a very rich flavour. I am not in a position to say anything about new Peas, as I have not tried any this season. I depend on about four varieties, which I know to be good. My earliest is

Chelsea Gem, quickly followed by William I., and for mid-season I find Duke of Albany and a selected strain of Ne Plus Ultra do well year after year. To follow Ne Plus Ultra I sow William I. again. I usually get good results from this sown at the end of July. I also grow Autocrat for a late crop. This is sown about the middle of July.—H. J. HARVEY, *Frampton Court Gardens, Dorchester.*

The varieties I consider best for the locality amongst the earliest are Veitch's Early Selected and Ringleader, to be followed by William I. and Exonian. Veitch's Earliest Marrow is an excellent Pea, and Laxton's Gradus cannot be too largely grown on account of its fine Marrowfat qualities combined with earliness. My best varieties, taking into consideration cropping and table qualities, are Duke of Albany and Veitch's Maincrop, which if sown at intervals give a good supply until the end of the summer. With these might be mentioned Autocrat and Stourbridge Marrow.—THOS. BENNETT, *Sharlington Hall.*

The best earliest are William I. and Day's Early Sunrise. The latter is a heavy cropper, producing large, well-filled pods and Peas of fine flavour; the best mid-season, Telephone, Duchess, and Duke of Albany. The first-named is much in request and extensively grown. Of late varieties, Ne Plus Ultra, British Queen, Champion of England, and Emperor of the Marrows are the best. The above four varieties, if sown from May 5 to May 18, will afford a regular supply of useful Peas well through autumn. A sowing of an early sort made during the first week of June will give a supply till the late autumn.—S. LAIRD, *Kinward Castle, Brechin, N.B.*

In reference to Pea growing, I have now had forty-five years' experience in the Sherborne Castle Gardens, and have devoted a deal of time to the trials of new Peas as they were sent out. Some turned out to be an improvement on older varieties, some were not. I think the very best that has come under my notice as an early variety is Exonian, and that will be my early Pea for the future. It is a wrinkled variety, fairly sweet, and a good cropper. I sow it at intervals of ten days from about the middle of February up to the end of March. Then I commence with Chelsonian, which is also a good cropper, very sweet, and, what is still better, it soon fills the dish. It has a good hardy constitution, and suits our soil well. From the middle of May to the end of June I sow Ne Plus Ultra, which will take a lot of beating. Were I confined to one sort for the season I should select Chelsonian. It is not like a good many of our new varieties—all outside show and nothing inside, but a good all round Pea.—W. G. PRAGNELL, *Castle Gardens, Sherborne.*

I have tried a lot of different sorts of Peas, but the best early is William I. For mid-season, Empress of India, Magnum Bonum, Eureka, and Autocrat are all good reliable sorts. For late work nothing beats Ne Plus Ultra.—W. A. MILLER, *Underley, Kirkby Lonsdale.*

I consider Duke of Albany the best Pea grown at the present time. It has been grown in these gardens, to my knowledge, for the last nine years and in the worst of seasons it always holds its own. For first earliest I like Veitch's Earliest Marrow, William Hurst, William I., and American Wonder. I always think it is best to grow several early varieties, as in some seasons some varieties will do much better than others. The best mid-season varieties are Duke of Albany, Maincrop, Gladiator, and Veitch's Autocrat. Of course, some do much better in some seasons than others, but I think the above are all good sorts both for cropping and flavour. For a supply in late autumn I think Autocrat, Ne Plus Ultra, and Sturdy are good varieties. Of course, in a very hot, dry season we cannot expect Peas to do well. Some kinds of Peas do well on some ground where other kinds would not do at all. The thing is to find the kinds of Peas that suit your ground. I always sow my Peas for autumn supply about the end of May or the beginning of June. There are large quantities of Peas grown in this district

in the fields, and the variety which is a favourite with one and all is Prince of Wales.—WILLIAM CONWAY, *Abberley Hall, Stourport.*

DESTROYERS.

GARDEN FRIENDS AND FOES.

ALTHOUGH quite sure of my statement when writing of the partiality of bees for ripe fruit, I am much obliged to those readers who have corroborated the same, and in answer to one who inquires as to whether this season is exceptional in the matter, can state that it has come under my notice more or less for at least twenty-five years. I remember an old gardener, famous for his outdoor Peaches and Plums, first calling my attention to it. It happened in this instance that some hives were placed on the other side of a Plum wall, and careful watching showed the insects dropping over the top and straightway tackling the fruit. So far as the insect and animal life generally associated with gardens is concerned, I think the gardener who has made a study of his business is fairly well acquainted with their ways and habits. Our enemies alike in variety and numbers are much more numerous than our friends. Constant watchfulness, the determination to be first in the field, acting on the principle that "prevention is better than cure," is the first consideration, and this, as noted above, involves a knowledge of the habits of the enemy as well as the time and mode of attack—facts sufficient to show that a good and successful gardener is of necessity a keen observer of all things around him both in the plant and animal kingdom, and those of us who may be a bit slack in this direction have it forced upon us by circumstances. It took, for instance, a couple of seasons to make me understand that the tapping of three-parts grown, green, uninviting-looking Cornish Gilliflower Apples by blackbirds was a premeditated act; but so it was, and for the last three or four years I have enclosed the tree, a large bush, with netting quite early in the season, and it has to be enclosed, too, with scrupulous care, for if a small hole is left the birds will find their way inside. In places where rats are occasionally troublesome, now that outdoor food is getting scarce, it will be well to examine carefully all outside portions of vineries with the view to prevent ingress. (I was caught napping last year, and had nearly twenty good bunches spoiled in the one night.) Any holes must be stopped with material the rats are not likely to scratch out, and if it is found necessary to leave a little air on front sashes, some perforated material must be fastened to the frames for the time being that will at once admit the air and keep out the enemy.

In no case does the anticipation of attack by an early crippling of the foe need more careful watching than with earwigs and red spider. I was called in to see some Gooseberry bushes in the early part of the present year that were reported dying, and that certainly appeared in a sorry plight. The cause was not far to seek; all the wood, with the tiny pair of leaves and the bud just emerging, was alive with red spider, that had already reduced the leaves to a state of semi-transparency. With the cause discovered, the remedy was soon provided. Instructions were given to mix certain quantities of soft soap and paraffin in hot water and apply the same in the proportion of a little over a wineglassful to three gallons of water, and to wet thoroughly every portion of the wood, and to return to the attack a second and a third time. It is almost needless to say that the

remedy was effectual, and the young foliage soon grew away clean and healthy. At this season of the year, when cleaning has already commenced in fruit houses and will be continued now until the last of the Grapes are cut, the same thoroughness should characterise the proceedings. Gardeners who have the misfortune to succeed to places that have been abandoned to the tender mercies of some insect it is difficult to dislodge, as bug inside and American blight out, are well aware of this. Cleaning will specially need attention inside after the hot, dry summer in the case of thrips and red spider, which have been very numerous and committed great havoc at the time of the ripening of fruit, when syringing was no longer practicable.

E. BURRELL.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 22.

As was to be expected, there were comparatively few exhibits before the various committees, the principal flowers shown being Chrysanthemums in their varied forms, with some good varieties of Orchids.

Orchid Committee.

Awards of merit were given to the following—

CALANTHE LAFRANCOI.—A hybrid raised at Burford Lodge. The parentage is unrecorded. It is remarkable for the individual size of the flowers as well as the unique colouring. The sepals are almost white, the large lip white, slightly suffused with rose, with some yellow on the disc. The plant carried a raceme upwards of 3 feet long, which bore quite two dozen flowers. It is a distinct and desirable variety. From Sir T. Lawrence, Burford Lodge, Dorset.

CYPRIPEDIUM ARGO-MORGANÆ.—A secondary hybrid derived from the parents indicated in the name. The dorsal sepal is white, suffused with green in the centre, and is veined from the base upwards with dark green lines. There are a few brown spots at the base. The petals have the drooping characteristics of *C. Morganæ*, pale green at the base, suffused with rose-purple at the apex. The whole is thickly covered with large dark brown spots, with numerous purple hairs on the margin. The lip is brown-purple, shading to green. From Sir T. Lawrence, Bart.

DENDROBIUM FORMOSUM LOWI.—A hybrid derived from the two species indicated in the name. The sepals are white, suffused with a peculiar buff shade of colour, the lip white in front, shading to yellow on the side lobes. Through the centre it has a suffusion of rich orange, and on either side, lines of the same colour. It has the intermediate characteristics of the two species.

Mr. J. Bradshaw, The Grange, Southgate, sent a choice group. The most prominent feature was a finely-grown plant of *Cymbidium Winnianum* (*giganteum* × *eburneum*) with nine spikes of flower. The sepals and petals are creamy white with a slight brown suffusion at the base, the lip creamy white with some yellow in the centre, and thickly covered with dark reddish brown spots. A grand dark form of *C. Traeyanum* with twelve flowers was also included. Several finely-flowered plants of *Oncidium varicosum*, a grand plant of *O. tigrinum*, several dark forms of *Cattleya labiata*, a pretty form of *C. maxima* with six flowers, and two pretty forms of *C. Mantini* (*Bowringiana* × *Dowiana*) were also shown. In *Lælio-Cattleya Apollonia* the sepals and petals are pale rose, mottled with white, the front lobe of the lip rich velvety crimson margined with white, the side lobes rose, lined with yellow and suffused with brown at the base. The plant exhibited carried a raceme of five flowers. Several finely-flowered plants of *Sophranitis grandiflora* were also included. A silver Banksian medal was awarded. Mr. H. T. Simonds, Woodthorp,

Beckenham, sent a choice and interesting group, consisting of finely flowered *Oncidium varicosum*, *O. tigrinum*, *O. Forbosi*, *O. pratense*, and *Cymbidium Traeyanum* with an eight-flowered raceme. Several finely flowered *Odontoglossum grande*, good forms of *O. crispum*, a pretty spotted form of *O. Andersonianum*, *Sophranitis grandiflora*, *Lycaste Skinneri*, and *Masdevallias* were well represented. Good forms of *Cattleya labiata* and numerous hybrid *Cypridiums* were also included. A grandly flowered plant of *Angraecum Leonis* with eight flowers was most attractive. Mr. H. Holah, St. Mary's Nursery, Richmond, sent a pale form of *Lycaste Skinneri*. Messrs. J. Veitch and Sons sent *Oncidium picturale*, resembling the natural hybrid, *O. praestans*. The sepals and petals are brown barred and mottled with brown, the broad lip yellow with prominent, raised, dark brown spots on the disc. Sir William Marriott sent a pale form of *Lælio-Cattleya Clonia* (*C. gigas* × *L. C. elegans*). Sir T. Lawrence sent a hybrid *Cypridium* of the *C. bellatulum* section, in the way of *C. Chapmani*, with two flowers, and a remarkably fine plant of *Calanthe Bryan*, the bulb being 8 inches in circumference, the plant carrying a raceme nearly 4 feet long, covered with its white and dark purple flowers. In *Cirrhopetalum appendiculatum* the upper sepal is pale green lined with purple, the outer edges and apex covered with rich purple hairs. The lower sepals are each 6 inches long, the exterior pale green mottled with purple; the interior, which is only visible at the base, rich purple. The petals are pale green with a line of purple. Mr. J. T. Bennett-Poë sent cut racemes of a remarkably dark form of *Oncidium tigrinum* and a fine variety of the lovely *Aerides Lawrenceæ*, the flowers well developed and fine in colour.

Floral Committee.

A first-class certificate was awarded to—

EPHYPHYLLUM TRUNCATUM PRINCESS, of which two plants were shown. The heads of growth were not especially large, but more erect than is usual with varieties of *E. truncatum*. The blossoms, which were of medium size and good form, are of a satiny white, shaded with soft salmony blush. From Mr. William Bull, King's Road, Chelsea.

The following received the award of merit—

CHRYSANTHEMUM MRS. BARKLEY.—A Japanese kind with very broad and stout florets broadly overlapping each other, and forming a very striking and distinct bloom. From Lady Byron, Thrumpton Hall, Derby (gardener, Mr. H. Weeks).

CHRYSANTHEMUM CHATSWORTH.—A distinct flower, the rather short florets spreading out and forming a good-sized bloom that is very full to the centre. The colour is white and deep rosy lilac. This variety was shown by Messrs. Cannell and Sons, Swanley, Mr. Wells, Reigate, and Mr. Godfrey, Exmouth.

CHRYSANTHEMUM GOLDEN SHOWER.—A curious development in so-called decorative kinds, the gold and chestnut florets drooping to some length, and singularly fine and thread-like in texture. From Mr. J. H. Witty, Nunhead Cemetery.

CHRYSANTHEMUM BEAUTY OF SHOLING.—A fine showy kind of a deep bronzy hue. From Mr. W. Wells, Reigate.

CHRYSANTHEMUM EARLSWOOD BEAUTY.—This is a single kind, with large spreading florets of a creamy white. From Mr. Wells.

CHRYSANTHEMUM DAISY BRETTE.—Also a single, the flowers pure white. From Mr. W. Wells, Reigate.

The most noticeable group upon this occasion was the magnificent arrangement of blooms set up by Mr. Norman Davis, Framfield, Sussex. Not only were the blooms of the highest excellence—certainly none so good have been seen at the Drill Hall this season—but the staging and general arrangement elicited the greatest praise. There was no formal arrangement of the blooms, and thus a grand effect was secured. Many kinds

were arranged in baskets, with trails of Smilax and an occasional bit of Bracken most tastefully inserted here and there. In the baskets were Mrs. J. W. Carter, with thread-like florets; King of Plumes, rich deep golden, and such singles as Eucharis and others, spreading out in most artistic fashion. Small vases were filled with Framfield Pink and the rich yellow Clinton Chalfont, while none showed to better advantage than the late bronze Tuxedo—a very fine shade, even now none too plentiful. Massive vases of Oriental pattern were filled with grand blooms of Mrs. Hermann Kloss, a rich bronze and chestnut shade; and Richard Dean, a fine crimson, while at either end tall standard vases, the latter alone nearly 4 feet high, contained splendid blooms of Western King, very pure and superbly finished. These, save for a few twigs of bracken, were alone in these, and ever all had a really fine effect. The great attraction was some six dozen magnificent blooms of Mme. Carnot, faultless in form and finish. These were staged in the usual stands at intervals in dozens round the group, and attracted the attention of all. Equally good were some of G. J. Warren, the yellow sport from the last named, the same high finish pervading all. Beyond the grouping and arranging of the blooms, which were artistically carried out, but few plants were employed, a few light Palms, chiefly Cocos, and small Crotons and Carexes being the only things intermingling with the blooms. This highly artistic arrangement was deservedly awarded the society's small gold medal. A very fine mixed arrangement came from Mr. H. B. May, Edmonton, prominent in which were some forty different kinds of *Dracæna* of a useful size and well grown. Some of the most distinct were *Sanderi*, *Jamesi*, dark metallic red, very compact; *Frederici*, *Triumphans*, *Orton*, *Renardæ*, a handsome kind with broad foliage; *Mme. Heine*, dark green margined white, very distinct; and *Lord Wolseley*, a more erect-leaved kind and very showy. A pleasing lot of the newer *Aspleniums* included *A. Mayi*, *A. Baptisti*, *A. ornatum*, *A. divergens*, *A. apicidens*, *A. Villardi*, very distinct and dwarf, and *A. V. facile*. A nice lot of *Bouvardias* in flower included *President Cleveland*, *Priory Beauty*, *Hogarth fl.-pl.*, *Alfred Neuner*, *Vreelandi*, &c. In another position a group of the varying forms of *Davallia fijiensis* was noted, some half-dozen of these together showing well their distinctive characters. Fine flowering examples of *Begonia Gloire de Lorraine* were very bright, and arranged amid *Adiantum Farleyense* and other choice subjects were very effective (silver-gilt Banksian medal). Mr. W. Wells, Earlswood, Redhill, staged a capital lot of *Chrysanthemums* in all the sections, very fine being *John Pockett* (crimson), *Surpasse Amiral*, *Chatsworth*, *Mrs. White Popham* (a variety that has received honours in every direction this season), *Pride of Ryecroft*, *Le Grand Dragon* (fine yellow), *Lady Hanham*, *President Bevan*, *Mr. T. Carrington*, *Nellie Pockett*, a fine white incurved Japanese, and *Mrs. C. Brown*, pure white, said to be a good market variety, though this is scarcely indicated in the form the petal has taken (silver Banksian medal). From Mr. T. B. Haywood, Woodhatch, Reigate (gardener, Mr. Salter) came a very fine lot of blooms, clean and fresh-looking. Among the most important were *Mme. Carnot*, *Miss Elsie Teichmann* (creamy yellow), *M. Chenon de Leche*, *Golden Gate*, *Australie*, *John Pockett*, *Lady Ridgway*, *Mary Molyneux* (a fine pink), *Mme. A. Rousseau*, *Mme. Rozain* (blush), *Nellie Pockett*, *Chas. Davis*, *Vivian Morel*, very fine, and *C. B. Haywood*, a beautiful white, being among the finest of those staged (silver Banksian medal). A capital lot of *Chrysanthemums*, embracing several sections of the flower, came from the Dowager Lady Freake, Fulwell Park, Twickenham (gardener, Mr. A. H. Rickwood). In this lot several good *Anemone* kinds were noted (silver Banksian medal). An exceptionally fine lot of incurved blooms was sent from Twyford by Mr. F. W. Flight, Cornstiles (gardener, Mr. W. Neville). This exhibit included some four dozen

blooms of the finest description, many of them faultless both in form and finish. Of this number is *Ma Perfection*, a really splendid white; *Globe d'Or*, *C. H. Curtis*, *Major Bonaffon*, *Topaz Orientale*, *Princess of Wales*, *Mlle. Lucie Faure* and *Robert Petfield* (silver Banksian medal).

Messrs. Cannell and Sons, Swanley, likewise contributed a fine display of these popular flowers, large vases of decorative kinds being more noticeable here than elsewhere. Of these note should be made of *Miss Harvey*, a capital white and very pure; *Alice Carter*, *Mrs. J. Carter*, *Pride of Ryecroft*, *Mrs. Filkins*, *Earlswood Beauty*, *Surpasse Amiral*, *Australie*, *Chatsworth*, *Autumn Glory*, *Mlle. Lucie Faure*, and others (silver Flora medal). Mr. W. J. Godfrey, Exmouth, Devon, had a good display of mostly Japanese kinds, *Lord Celeridge*, yellow; *King of Buffs*, *Miss L. D. Barry*, white; *Louis Dalle*, a splendid bronze; *Kudd's Red*, *M. Fatzer*, golden-yellow, very fine; *Georgina Pitcher*, good yellow; *Orphée*, a Japanese *Anemone*, creamy white; *Grand Mogul*, &c., being among the better blooms. Mr. J. C. Garnier, Rookesbury Park, Fareham (gardener, Mr. N. Molyneux), had a few blooms of *Earl Crawford*, lilac-blush and purple; *Nellie S. Threlfall*, white incurved; and *Golden Gem*, an incurved of fine colour, but lacking size. *Lady Byron*, *Thrumpton Hall*, Derby (gardener, Mr. H. Weeks), had a fine assortment of *Chrysanthemums*, in which the pink and lilac shades predominated. Very good were *Mrs. Cursham*, softest lilac; *Henry Weeks*, crimson and gold; *Mrs. Coombes*, lilac-pink; *Miss Maud Douglas*, rose-lilac; *Little Nell*, white; *Edith Dashwood*, blush; and *Annie Prevost*, rose-amaranth. Messrs. T. Cripps and Son, Tunbridge Wells, had a large half-circular group of *Poinsettias*, margined with small plants of *Eurya latifolia foliis-variegatis*. The *Poinsettias* were a highly creditable lot of plants, singularly uniform in the size and colour of the substantial and brilliant bracts. The foliage, too, was in every way excellent, and retained to quite a low level on the plants (silver Flora medal). A basket of plants in flower of *Ornithogalum lacteum* was shown by Sir Trevor Lawrence, Burford Lodge, Dorking (gardener, Mr. Bain). This is a useful species requiring only the ordinary greenhouse treatment to grow the plants successfully. The heads of blossoms are arranged in a way similar to those of *O. pyramidale*, but with larger individual pure white flowers. Messrs. Veitch and Sons, King's Road, Chelsea, had three of the hybrid *Begonias*, the result of crossing the tuberous kinds with *B. socotrana*, *B. Myra*, *B. Ensign*, and *B. Winter Cheer* resulting therefrom; the last is a semi-double and perhaps the most showy of this class at the present time. A very strange development in the single *Chrysanthemum* came from Mr. Witty, Nunhead, the florets drooping to a length of 6 inches, of which the tubular portion is fully 4 inches long and very fine, the more strap like end extended and terminating in a twice or thrice folded curve, thus rendering it a great curiosity. *Begonia venosa*, from Brazil, was sent by Mr. Gilbert Christy. It is one of the woolly-leaved species, producing spikes of small white flowers. A strange characteristic of the kind is the skeletonised sheaths that clothe the stem and from which the leaves emerge. The species is frequently imported with collected Orchids, seedlings quickly appearing when the plants are placed in warmth.

Fruit Committee.

An award of merit was given to—

APPLE BALLINMORA PIPPIN.—A very nice looking dessert Apple, above medium size, and with a pleasant flavour. It is a somewhat conical fruit, with depressed eye and almost entirely covered with crimson, flesh white and firm. This should keep well and will be a favourite market fruit for its shape and splendid colour. From the Messrs. Hartland and Sons, The Lough Nurseries, Cork.

Messrs. Hartland also staged another new Apple named *Ahern Beauty*. This was conical

and of a deep crimson colour, not unlike *Crimson Queening*, but of no special quality. Mr. A. Ward, The Gardens, Stoke Edith Park, Hereford, sent a very pretty seedling Apple named *Lady Emily*, beautifully coloured and evidently a good keeper, but not at its best. This will be sent again in better condition. Mr. Williams, Lower Eaton Gardens, Hereford, sent a new Apple *Sir Joseph*, a very nice fruit, but the committee did not think it any improvement upon older well-known kinds. Mr. J. C. Tallack, Livermere Park Gardens, Bury St. Edmunds, sent a new Apple. In appearance it is not unlike *King of the Pippins*, but quite different in the flesh, being a softer and richer fruit. The fruits sent were past their best and the committee desired it to be sent again earlier in the season. A seedling Apple came from Mr. W. J. Clark, Manor House, Binbrook, Market Rasen. This was doubtless the *Curtail*, an old variety, and one of second-rate quality. Another Apple, a supposed seedling, not unlike *Lemon Pippin*, but of very poor quality, came from Mr. G. Rawlins, Whitebrook, Monmouth. Some excellent Onions of a new variety called *Ne Plus Ultra* were sent by Mr. L. J. Dunbar, The Heath Park Nurseries, Hemel Hempstead. We have seen larger bulbs, but none of better shape and finish. Though somewhat like *Ailsa Craig* in shape, this variety is stated to be a much longer keeper. The committee desired that the bulbs be sent to Chiswick till next April to test their keeping properties.

NATIONAL CHRYSANTHEMUM SOCIETY.

The floral committee of this society held a meeting on Monday last at the Royal Aquarium, Westminster, when the chair was taken by Mr. Harman Payne. The attendance of members was slightly under the average, owing no doubt to the very bad state of the weather, but the exhibits were in general of a high order of merit.

The leading contributions came from Messrs. Cannell and Sons, Mr. H. J. Jones, Mr. W. Wells, Mr. H. Weeks, Mr. W. J. Godfrey, Mr. Witty, Mr. Forbes, and Mr. N. Molyneux. Mr. G. W. Forbes staged a most attractive collection of large and very pretty-looking single-flowered varieties, and from Mr. H. Weeks there came a grand display of sixty blooms of his new seedlings, to which the committee awarded a small silver medal. Mr. Witty sent some of his curious novelties from Japan, and was accorded a vote of thanks for the same.

First-class certificates were awarded to the undermentioned novelties, viz. :—

CHRYSANTHEMUM CHATSWORTH.—A colonial Japanese, often met with in excellent form during the present season. It has long drooping florets, and the colour is a fine rosy purple on a white ground. From Messrs. H. Cannell and Sons.

CHRYSANTHEMUM FLORRIE.—A single-flowered variety, of good size, having ray florets of a bright rosy pink. Shown by Mr. G. W. Forbes.

CHRYSANTHEMUM VICTORIA.—Also a single, with rather broad, long florets, blooms large; colour pale sulphur-yellow. Another of Mr. Forbes's.

CHRYSANTHEMUM EDITH DASHWOOD.—A large Japanese, with very narrow intermingling florets, forming a flower of great depth and very close in build; colour a very delicate shade of pale lilac-pink. From Mr. H. Weeks.

CHRYSANTHEMUM MRS. BERKLEY.—This is a noble solid-looking Japanese of great size. The florets are rather short, but very broad and lie close together, forming a kind of tight reflexed flower; colour bright lilac-mauve. Also from Mr. Weeks.

Other meritorious novelties were *Miss Maud Douglas*, of the Mrs. C. Harman-Payne type; *Annie Prevost*, rosy purple; *Little Nell*, a large white; *Mrs. Combe*, *Mrs. Cursham* and *Emily Tower*, all of the Japanese section. *Edgar Forbes*, terra-cotta; *Mrs. Forbes*, white; *Maud Pitcher*, yellow; *The Sirdar*, terra-cotta; *Crown Jewel*, golden yellow, and *Mrs. J. Watson*, bright

rosy pink, with a white centre, are all very attractive and promising singles of good size and of much service for cutting. New incurved compressed Earl of Crawford and Miss Nellie Threifall, a large creamy white. A new Japanese Anemone Mrs. P. R. Dunn, colour white, was also regarded as a useful addition to its class.

Gardeners' Royal Benevolent Institution.

—We are asked to state that Mr. F. G. Treseder, chairman of the Carliff Chrysanthemum Society, has forwarded a cheque for £5 15s., being the amount realised at a stall held at the recent Chrysanthemum exhibition at Cardiff in aid of the above institution.

NOTES OF THE WEEK.

Citrullus colocynthus (Colocynth).—Plants of this species from Tropical Africa are now bearing many ripe fruits in one of the houses in the Royal Gardens, Kew. The fruits in question are about as large again as an ordinary Orange, and being of a rich golden hue, are of a very showy character.

Datura sanguinea.—A large example of this greenhouse shrub is now flowering abundantly in the greenhouse at Kew. It is when the plants attain the dimensions of this one that flowers come abundantly. At the same time, these older, and therefore larger, examples can only be accommodated in structures of the largest size.

Jasminum grandiflorum.—Though by no means an abundant bloomer, there is ever a welcome and delightful fragrance in the vicinity of this species when a few blossoms are expanded; so few, indeed, they may scarcely be seen. Of such fragrant plants as these one never tires, the purity of the blossoms and the never-failing perfume being always admired.

Begonia Haageana.—Few of this variable genus produce larger or more conspicuous heads of blossoms than this, the flowers being of a distinct character and very showy. Externally the blooms are covered with spines, and these, coloured with a pinkish hue, are very attractive by reason of their numbers. The foliage, too, is handsome and of a free-spreading character.

Cassia marilandica.—This well-known plant, so long regarded as a greenhouse subject, and more recently as suitable for the open air, was noted lately flowering freely against a wall in what at eight did not appear the most suitable position. The clusters of yellow blossoms had, however, been numerous, and the plant withal of large size and in good health.

Primula capitata.—In one or two instances recently, seedlings of this have been inclined to bloom, which is not calculated to improve the subsequent flowering. It is unfortunate it should do this now and again, and there appears no safeguard against it. The plants are evidently influenced by the season, and it matters little whether planted out or in pots, the result is much the same.

Mandevilla suaveolens seedling. — This sweet-scented creeper has flowered beautifully on a wall with a south aspect. This is not unusual, but this year it has borne numerous seed-pods for the first time. It grows freely in light garden soil, and may be planted under a south wall in warm districts where it will hardly need protection.—W. O., *Fota*.

Calliopsis aurantiaca.—Several examples of this very singular and interesting plant have been flowering in the No. 7 range at Kew quite recently. It produces a scape at least 2 feet high from the bulb and a curiously arranged umbel of orange-gold flowers, from which the numerous stamens protrude to about three or four times the length of the corolla, the whole forming a perfectly umbellate head and of a distinct character.

Crocus sativus Haussknechti.—Among the autumn-flowering Croci this is a veritable gem, and as good as it is distinct; indeed, so far as the latter point is concerned, it is scarcely likely to become confused with any other at present in cultivation. The colour is pure white. Few kinds could have a prettier effect than this one at this season, and if planted over a thin carpet, as, for instance, some of the Arenarias, the flowers would be kept clean.

Wulfenia Amherstiana.—This is one of those singularly beautiful plants that is not at all common. The genus itself is also small, and only includes a few

kinds, *W. carinthiaca* and the above being the most important. These plants are rather partial to a cool, shady position and a peaty soil. Under these conditions the plants bloom somewhat freely, the spikes, which are each a foot or more long, bearing a great number of the rather quaint flowers of a purple-blue colour.

Yucca gloriosa flowering.—In consequence of the hot, dry summer Yuccas have flowered much more profusely than usual, and are still showing bloom-spikes, only to be destroyed by damp and frost. Some plants had as many as ten spikes of flower open at one time, reaching 5 feet above the crown of the plant. A single plant on grass has a fine effect, but the flowering mars the beauty of the plant for some years, as several shoots spring from the base of every flower-stem.—W. OSBORNE, *Fota*.

Saintpaulia ionantha.—By the amateur who desires an interesting display of flowering plants all the year round the above should be freely grown. In the matter of culture it presents but few difficulties, and by a little judicious management may be flowered continuously over a somewhat lengthened period. The plant is naturally a free and profuse bloomer, a fact that greatly enhances its value, and in the temperature of a warm greenhouse the intense violet-purple blossoms come in quick succession.

Polypodium nigrescens.—Included in the very interesting group of Ferns at the last meeting of the Royal Horticultural Society were examples of this by no means common species. In its general habit it is in every way a distinct as well as attractive Fern, the somewhat branching fronds spreading considerably and revealing a rather glossy surface. A marked feature of the kind, however, is the raised nipple-like excrescences formed by the fruiting spores, and so raised as to produce a very striking appearance.

Saxifraga apiculata.—A mild season net only gives us late flowers, but also brings into bloom considerably in advance of their normal time the plants of the early year. About November 14 the first flower of this early Saxifrage showed its sulphur-yellow petals quite opened. A slug was, however, on the watch for such a delicacy, and in a day or two cropped the flower. The plant is now bristling over with buds, and should open weather continue will have a good many open flowers in December.—S. ARNOTT.

Late Peas.—With the collapse of the Pea crop so early this autumn, I was not prepared to find such a good dish as that in a collection of vegetables staged at the Frome show quite recently. Mr. Morse, the gardener who staged them, said he had a succession of Peas this autumn until the middle of November. The variety was Autocrat and was sown about the end of June. I did not gather what were the conditions under which they were grown, but such fine Peas in the middle of November are valuable.—W. S.

Viola hederacea.—This has been giving a few of its unique flowers during the past few weeks, and very beautiful they are at this season. Little more than a couple of inches high, the rich blue and white flowers possess an exceptional charm so late in the year when even the most robust subjects are past and gone. The plant, so fresh and bright-looking now, will scarcely be able to stand the winter. In a frame that is airy and dry the plants may safely come through an ordinary winter, and care is needed to place some stock safely from the reach of frost, wet, and slugs.

Large single-flowered Chrysanthemums.—At the meeting of the National Chrysanthemum Society's floral committee on Monday last, a nice lot of seedling single-flowered sorts was shown, and, with one or two exceptions, called for special recognition. They embraced a pleasing variety of colour and the form was distinctly above the average. Florrie, a deep cerise-pink, with narrow florets of good length and yellow disc, was very taking, and Victoria, a lovely primrose-coloured flower, with long slightly drooping florets, was also good. It was mentioned that the seedlings which were sent by Mr. G. W. Forbes were from the well-known variety Purity.

Hypericum patulum.—The introduction of *Hypericum Moserianum* has done much to supersede *H. patulum* in gardens where there is not

space to grow a number of plants belonging to the same genus. It will be, I think, unfortunate if *H. patulum* should be left out in the cold by reason of the undeniable qualities of the hybrid *St. John's Wort*. As a rock garden shrub it has considerable beauty, its drooping habit of growth being very elegant. The flowers last long in bloom, though being protected from rain. In some winters *H. patulum* is killed almost to the ground here by frost, but in mild seasons such as last it suffers little, only the immature shoots of the current year's growth being killed. *H. patulum* is still covered with flower here.—S. ARNOTT, *Carse-thorn, by Dumfries, N.B.*

Apple Cornish Gilliflower.—I am pleased to record this year a very fair crop of this splendid Apple taken from an old bush tree about 12 feet high and the same in diameter. Few high-class Apples are so little known, doubtless owing to the fact that its shy bearing properties have long been proverbial. I think, however, two or three trees should always be included when planting, as the connoisseur in dessert Apples would place it absolutely in the front rank, and from a flavour standpoint it is quite equal to the best Ribston or Cox's Orange. It is an ugly-looking Apple in the green state, and it is, therefore, all the more strange that it should be one of the first to be attacked by birds. I can only account for this that even in this stage there is a certain aroma that attracts the birds. Not a sound Apple would ever be gathered if the tree were not carefully netted when the fruit is three parts its full size.—E. BURRELL.

Pieris mariana.—The Maryland Andromeda, or *Pieris* as it is, perhaps, more correctly called, is of high value at this season because of the brilliant blood-red of its dying leaves. This year other garden plants are much quieter in the colouring of their autumn tints than is usual here, but this *Pieris* is an exception, and has for some weeks delighted me by the glowing red of its foliage. Even if it did not give its white flowers earlier in the year it would deserve a place on account of its autumnal colour. In a partially shaded position in moist peaty soil this little North American shrub is of easy cultivation. My first acquaintance with it was made a number of years ago in a manse garden a few miles away, where it was highly prized by the worthy clergyman, who was devoted to his garden. I can well remember the pleasure with which he pointed out the Maryland Andromeda, then scarcer than it is now. Maund gives a comparatively poor plate of the flowers in the "Botanic Garden."—S. ARNOTT, *Carse-thorn, by Dumfries, N.B.*

A fine Yew.—Reference has been made to some famous Yews recently in THE GARDEN, particulars of which to many readers are very interesting. At Marston, near Frome, there is a fine specimen, the girth of which at 4 feet from the ground measures 27 feet 6 inches, its massive head having a spread of branch something over 50 feet. The heavy soil of Marston evidently suits this as well as some other trees of evergreen and deciduous growth. Yews being of such slow growth, a tree of such a size must have occupied its present site a long time, and at present there are no signs of decay. It would be, I presume, quite an impossibility to arrive at anything like an accurate estimate of its age from the measurements given. If the present system of naming trees by means of metallic labels had obtained years ago it would be a more easy matter to correctly estimate, but there are few instances where the record of planting is given in hygienic days. How much more interest would many a lawn afford if the name and date of planting of each tree were clearly marked on a good label.—W. S.

Apple American Mother.—Amongst the many notices of Apples that have appeared in THE GARDEN I have seen no mention of the above-named variety. The present season is my first experience with it, and I am sending you a sample to test its qualities. The tree is a free grower and bearer, the fruit the same in shape

and size as Worcester Pearmain, the colour a rich apricot-yellow ground, suffused with crimson, with darker streaks of the same colour all over the sunny side; the flesh yellowish white, very crisp, juicy, and sweet, with a very pleasant aroma. Its season is about the same as that of Cox's Orange, but it keeps much better than that variety. I think it is handsomer than Worcester Pearmain and better flavoured than Cox's Orange, which is saying a great deal for any Apple, and when better known I feel confident it will become more popular than that variety.—WM. SANGWIN, *Trelissick, Truro.*

* * More highly coloured samples of this Apple we have never seen, the flavour, too, being excellent, and we think quite equal to that of Cox's Orange.—ED.

Open air Chrysanthemums.—Not for many years have we had so prolonged a display of open-air Chrysanthemums, for even now (November 21) many of the open air blooms are better than those of the same varieties under glass. This is all the more remarkable, because early in October many that are now in full beauty looked as if they would never expand. During the prolonged drought of July, August, and September these plants drooped and looked far more dead than alive, but directly the welcome rain came at the end of September the buds began to swell and the foliage freshened up wonderfully, the exceptional mildness of the autumn enabling these plants to perfect an abundance of bloom. It would be well-nigh impossible to enumerate even the best of kinds for the open air, as all have done so well, but some of the oldest favourites like Cullingfordi, Mm. Lacroix, Val d'Andorre, Gloriosum, and others have been and still are grand. During the last few days I have cut splendid blooms of Niveum, Mrs. Canning, W. H. Lincoln, and others of the latest flowering sorts.—JAMES GROOM, *Gosport.*

The Tree Tomato.—I notice that on p. 417 "W. W." draws attention to the merits of *Cyphomandra betacea*. A fine specimen some 9 feet high, with spreading head studded in the summer with white flower-clusters, and later on with numerous orange-yellow fruit much resembling the fruit of the common Passion Flower, but rather more pointed, is indeed a noble sight, the size of its fully-developed leaves adding materially to its appearance. My impression as to the edible value of the fruit does not, however, coincide with that of "W. W.," for neither in a raw nor cooked state does it appear to me appetising, but this is merely a proof of how tastes differ. The leafage of the plant when brushed against or bruised emits a powerful and most pungent odour to which the smell of the bruised leaves of the true Tomato is comparatively pleasant. This, I think, is its chief drawback. Two large specimens were grown a couple of years since in a large Tomato house at the South Devon Fruit Farm, near Torquay, which fully proved the value of this plant as a decorative subject for culture in large glass-houses amongst other tropical or subtropical plants of noble habit.—S. W. F.

Frost at last.—It is, I should imagine, some years since there was such an absence of frost as occurred this autumn. Until the middle of November there was not sufficient here to check the growth and bloom of such tender plants as Dahlias; indeed, on the previous day my Dahlias were brighter and more full of flower than at any time this summer. Five degrees, however, on the 15th put an end to the flowers, and now the removal of the tubers to winter quarters can be proceeded with. The leaves of trees, particularly Elm and Oak, from the same cause are hanging late, many not showing signs of autumn colour, but remaining green. Lawns need the mowing machine to facilitate the work of sweeping, grass growing almost as freely as in summer. Some other forms of vegetation show signs of activity unusual at so late a period. Such an experience is very pleasant so far as it affects the time present, but misgivings as to future contingencies arise, for if a severe winter follows

so abnormally mild an autumn no one can anticipate future prospects. One can more easily reflect on the past and recall the great havoc committed by prolonged frost following milder times, when tender trees and vegetation became so hopelessly crippled.—W. S.

Campanula Portenschlagiana.—One of the numerous merits of Portenschlag's Bellflower is the prolonged period over which it blooms. After the first blooms are past I generally cut the plants over and have flowers until late in the year. As I write on November 21, several plants have a considerable number of blooms open and forming welcome bits of blue on the fresh green leaves. For covering crevices between the stones nothing can give more pleasure than this Campanula, especially if these crevices are vertical or horizontal openings on the face of large surfaces of rockwork. The plants cover these admirably. For old walls there is no better Campanula than this, as its long thick roots ingratiate themselves into the smallest crevice and make room for themselves. I knew a greenhouse on which *C. Portenschlagiana* has completely established itself between the joints of the brickwork. It looks very pretty there, and its presence in such a position is suggestive of other uses to which it might be put. The large flowered variety, known in the trade as the Bavarian variety—although not, so far as we know, a native of Bavaria—is superior for most purposes. *C. Portenschlagiana* seems quite as much at home on shady rockwork as on that with a sunny exposure.—S. ARNOTT.

Cephalotus follicularis (New Holland Pitcher).—It is perhaps not generally known how hardy this Pitcher plant is. It has come safely through one of the severest winters experienced during the last twenty years or so with cold frame treatment and no other protection but a mat covering the frame. It is possible, however, that the pitchers may not reach their largest size, as the plants do not start so early into growth. All the same, however, they do attain to a very considerable size and the strongest plants also flower occasionally, while the bronzed appearance of both pitchers and leaves is more usual under the cold treatment than when the plant is grown in the greenhouse. In other respects the details of culture are similar, the plant succeeding in peat and chopped Sphagnum Moss freely intermingled with broken brick rubble or the like. Firmly potted in this mixture and the plants slightly mounded to the centre they may be plunged in Moss or cocoa-nut fibre in the frame to their full depth. During winter the plants require but little attention. A very interesting group of things requiring similar care may be thus grown, such, for example, as *Dionaea muscipula*, *Sarracenia purpurea*, *Darlingtonia californica*, the more hardy Sundews and the above. To these may be added *Goodyera pubescens*, a beautifully marked plant that is not often seen.

Teucrium fruticans.—One of the most conspicuous shrubs in the rock garden at the present time is *Teucrium fruticans*, the Tree Germander. It is usually classed as a greenhouse or half-hardy shrub, but is, I believe, hardier than is generally supposed. I had no knowledge of it until rather more than two years ago, when I saw small plants in the rock garden in the Royal Botanic Gardens at Glasnevin, Dublin. At that time I was pleased with its appearance by reason of its white or silvery branches, and the green colour of the upper surface of the leaves contrasting with the white tomentum below. The blue flowers, although not conspicuous, were attractive also, so that I was glad to have the opportunity of growing this *Teucrium*, although, as I might have discovered on reference, it grows taller than I had expected. On a second inspection of the Glasnevin plants this year, I found that they had grown considerably and had formed fine bushy plants 18 inches to 2 feet high. Left uncontrolled the Tree Germander has a tendency here to throw up long branches 4 feet or so in length. I think, however, that this shrub ought to be cut back after flowering to secure bushy plants. Unless I am mistaken this is done at Glasnevin. I grow this

Teucrium on a dry, sunny position with a full south exposure, and sheltered from cold north winds by a wall. *T. fruticans* has been introduced from South Europe for about thirty years and grows readily from cuttings.—S. ARNOTT, *Carschothorn, by Dunfries, N.B.*

The value of fowls' manure.—In addition to the good uses to which this valuable manure may be put, as mentioned by "Norwich" (p. 380) should be included that of applying it in a liquid state as an occasional stimulant to Vines and Peach borders. For this purpose take half a barrow-load of the manure, throw it into 100 gallons of water, and allow it to settle for a few days, when it will be ready for use. As a rule this quantity of water would not require to be further diluted before use, but much depends on the length of time the manure has been accumulating. If considered to be too strong, it can easily be toned down by the addition of more water. The value of fowls' manure is not appreciated nearly so much as it should be, and where practicable it should always be saved, placed on one side for use in the garden, and kept in a dry place until wanted.—A. W.

The weather in West Herts.—Since the 16th there has been a gradual decline in temperature. On that day the highest reading in shade was 61°, whereas to-day (23rd) the temperature has at no time risen above 39°. Then, again, on the night of the 16th the thermometer exposed on the lawn never fell lower than 47°, whereas last night the same thermometer showed 13° of frost. The latter is the greatest cold as yet recorded here during the present autumn. The underground temperatures have also fallen considerably during the week, the thermometer at 2 feet deep having fallen 4°, and that at 1 foot deep as much as 10°. At the present time the soil is about 2° warmer than is seasonable at 2 feet deep, and, on the other hand, about 3° colder than is seasonable at 1 foot deep. This is the first time for more than three months that I have had to record a ground temperature of less than average warmth. Until to-day (23rd) very little rain had fallen for nearly three weeks, and for the last week of that period no measurable quantity of rain-water has come through the soil in either percolation gauge. For a short time on the morning of the 23rd the ground was covered by snow, this being the first fall of the season. During the fortnight ending the 20th the winds remained light, the mean velocity for that period being only 3½ miles an hour. On the 22nd the sun shone brightly for 6½ hours, which is a splendid record for so late in the month. All my Dahlias were killed by the frost above-mentioned—that of the night preceding the 23rd, which is three weeks later than the average date of their destruction in the previous thirteen years, and with one exception (1894) later than in any of those years, but only four days later than last year. In 1897, however, the plants only lingered on in a crippled condition after the injuries they had received from frost on October 7 until completely destroyed, whereas this year many of them were flowering with tolerable freedom until overtaken by the frost of the 23rd inst.—E. M., *Berkhamstead.*

Pears for succession.—Will you kindly tell me the six best Pears for succession on walls?—J. L. L.
* * * Louise Bonne of Jersey, Thompson's, Marie Louise, Winter Nelis, Glou Moreau, and Josepaine de Malines.—ED.

Cotoneaster vulgaris.—Years ago I used to gather *Cotoneaster vulgaris* on the Great Orme's Head, but it seems now to be extinct. If any of your readers possess a plant from this locality, they would greatly oblige me by giving me a cutting.—SPENCER H. B. KHAM, *Underdown, Ledbury.*

Names of plants.—S. H. B.—*Datura ceratocaulon*.—S. F. H.—1, *Cupressus Lawsoniana*; 2, *Symphoricarpos vulgaris variegata*; 3, *Juniperus phoenicea* (?); 4, *Hypericum kalbianum*; 5, *Amelanchier vulgaris*; 6, *Ribes alpinum punibum*; 7, *Thuopsis dolabrata*; 8, *Cupressus thyoides variegata*.

CHRYSANTHEMUMS.

THE CHRYSANTHEMUM RUST.

IN some notes on "Chrysanthemums at Syon House" (p. 388) the writer states of the rust that "a few specks had been seen and as quickly and promptly destroyed." It would be interesting to growers if the writer of the note or Mr. Wythes himself would tell how the destruction of the pest was brought about, presuming, as I do, that it was first detected in its summer form. All the remedies I have tried have failed to arrest it in the slightest degree, and the general opinion of all growers whom I have met this autumn is that so-called remedies are useless when once the summer stage of the disease has been reached. Mr. Massee in giving the life-history of the fungus states that the summer spores are carried from one plant to another and germinate quickly. With regard to distribution in this way, it is curious to note that the spores develop on the lower leaves first, and that it is almost invariably the lower or under sides of the leaves which are worst affected. If the spores reproduce themselves so readily and are carried about so easily by one or other of the means which Mr. Massee suggests, why is it that they so very seldom germinate on the upper sides of the leaves? Now and then it is possible to find spores developing in such a position, but such cases are rare indeed when compared with the plenitude of disease spots to be found underneath the leaves. No one who knows the formation and general habit of the Chrysanthemum leaf as growing needs to be told that the under surface is by far the best protected from floating or falling spores or from any that are carried about in a casual way on the clothes of persons working among the plants. Among the plants growing here are many which have spores resting on the upper surfaces of the leaves as thickly as it is possible for them to rest, giving the whole of these plants the appearance of having been heavily dusted with snuff, yet in

but very few cases can I see any sign of growing spores on the upper surface, and where there are such to be found it is only where there are bigger patches of the rust immediately beneath them, which goes far to prove that the former are only a chance outcome of the latter.

There is nothing erratic in the progress of the disease upwards, as one would expect from floating spores; it goes steadily and surely on until the topmost leaves are reached, and this steady advance leaf by leaf, always in an upward direction, seems to point towards a probability of the disease in its summer stages being carried up in the tissues of the plant itself, and that it is not dependent on these spores for its development when once a plant has become affected. Terminal shoots, which have run up a foot or 2 feet beyond their fellows on the same plant, have no immunity from the rust, though their position keeps them well away from and above other affected shoots. I do not agree with "A. D." that salvation is to be found in dealing with the plants in a less artificial manner. Chrysanthemums have been grown for very many years under the system which now obtains, but the disease itself is new to the plant. Many cool-struck plants that have been naturally grown as bush plants without any but the simplest form of feeding, *i.e.*, by manure water given only after the roots have filled the pots, are as badly affected as others grown for big flowers. Surely this old-fashioned method of feeding (by natural manures), which has been in vogue for generations and on pot plants of almost all kinds, need not be given up, and would hardly render the plants disease-proof if it were. I should not be surprised to see the disease develop itself on plants grown wholly outdoors at any time, as there is good authority for accepting it as a native and one that attacks native plants. The Chrysanthemum as a winter flower under glass is too valuable to be dealt with so lightly as "A. D." suggests, and it is quite certain that its culture in that way will

not be given up until it is proved that no remedy will suffice to kill out the disease. One might almost as well give up growing Potatoes because of the Peronospora.

In some earlier notes I gave a list of the worst affected plants, and said that the rust had not apparently affected the prospects of good flowers, but these varieties have since opened poorly and the loss of foliage has certainly affected them. On the other hand, it is pleasing to note that some favourite varieties have come through practically unscathed, though they have been grown side by side with others that are bad and their leaves are studded with dropped spores. I give a list of these, as it would be interesting and valuable to know whether they can be relied upon to resist the disease, or whether it is only a chance exemption here. Possibly it will be necessary to select some such for growing extensively to the exclusion of others, as in the case of some Potatoes. Khama, Mme. Ad. Chatin, Edith Tabor, Princess Maud, Richard Dean, Mme. Marius Ricoud, E. G. Hill, Miss Mary Godfrey, Matthew Hodgson, Sunstone, Western King, and Mrs. F. A. Bevan are quite free, while those only slightly affected include G. C. Schwabe, President Borel, Mrs. H. Weeks, Edwin Molyneux, Charles Shrimpton, M. Pankoucke, Charles Davis, Viviani Morel, Boule de Neige, Hairy Wonder, H. L. Sunderbruch, Mme. C. Champon, Australian Gold, and Joseph Brooks.—J. C. TALLACK.

"A. D." is doubtless right in his contention (page 387) that naturally grown plants withstand this disease more readily than those that have been highly fed, but it is a question if he does not go too far in saying that rust does not affect plants naturally grown, but only "the pampered pets of the growers." It is quite possible—indeed, probable—that if they emerge from their greenhouse culture unaffected, the naturally grown plants will not contract the disease during their stay in the open, nor during their subsequent flowering under glass. But the mischief is often done by the introduction of contaminated cuttings that may rapidly infect their

neighbours in the early stages of their growth, when all, whether destined eventually for the production of show blooms or merely for ordinary decoration or for planting in the open, are undergoing identical treatment. The other day I heard of a case where the disease was introduced in this manner early in 1897, and proved so virulent, that all the plants were burnt and a fresh lot of cuttings procured for the present year's display. Again, however, were the germs present in the cuttings and the disease manifested itself, although by careful watching and isolation its effects were rendered less disastrous than in the preceding year.—S. W. F.

CHRYSANTHEMUMS AT FRAMFIELD.

NUMEROUS glass houses, each some three hundred feet in length, are filled with typical exhibition blooms, and when it is stated that some 12,000 plants are grown for stock and for market, readers will at once appreciate the extent of this gorgeous display. The most remarkable feature was the handsome blooms of Mme. Carnot, G. J. Warren (the yellow Mme. Carnot), and Mrs. W. Mease (the latest sport and of primrose colour). The two former predominated. Each of the flowers was up to exhibition standard, and this result was achieved by retaining second-crown buds and flowering the plants in 8-inch pots. Mr. Davis plunged his pots in the loamy soil of the greenhouse floor, and there is little doubt considerable benefit was derived by the roots in this way. A variety which it is thought will possibly rival the rich yellow form of Mme. Carnot is seen in a strong-growing Tasmanian seedling named J. R. Upton. This is a very large massive-looking flower on late buds opening in whorl form, with very long, broad, pointed florets of great substance. The growth is sturdy, and the plant is also fairly dwarf. The colour is best described as rich golden-yellow. Hundreds of plants of Western King, the pretty incurved Japanese pure white flower, were a pretty sight. W. Towers, a lovely canary-yellow Japanese with long fluted petals, was represented in handsome form, and in flowers resulting from second crown buds. This is a beautiful exhibition sort. Lady Hanham, the pretty cerise-pink and chamois sport from Viviani Morel, is of marvellous colour here, especially on late flowers, and here, too, there is at last a pure white sport from Viviani Morel, and sent out under the name of Mrs. Ritson. There is sure to be many inquiries after such an easy growing white sort, as members of this family are known to be. President Nonin does not come up to expectations of last season. Early flowers are rather thin, while late blooms are almost incurved in build. Of Chas. Davis and Viviani Morel, each by the way doing well this season, there were a goodly number, and each was represented in good form and colour. Richard Dean had been grown largely. This is best described as deep rich chestnut-crimson, with bronze reverse. First crown buds seem to suit this variety very well. Other Japanese sorts succeeding very well this season were N.C.S. Jubilee, coming very neat and even in form and of a very light silvery mauve colour; Fée du Champsaur, a fine exhibition white sort and making a grand full flower; Celeste Falconnet, a new continental sort, was seen in good form, with innumerable narrow flimsy florets of a rosy lilac colour. Joseph Chamberlain proves its value as a refined rich velvety crimson, with an effective bronze reverse. A new sort to be introduced in the spring is named John Bridgman. This is like a refined bloom of Etoile de Lyon colour, silvery pink. Numerous flowers of Lady Ridgway, a large salmon-buff incurved Japanese, were often in evidence; so, too, were Mrs. Hermann Kloss, Duke of York and John Neville. The refined blooms of Mrs. F. A. Bevan, of a silvery peach-pink colour, were much admired, as were handsome blossoms of Thos. Wilkins, Mrs. S. C. Probin and Chas. Shrimpton. In Mme. J. Chanre, another distinct acquisition to the heavy-petalled varieties, the colour on the inside of the petals is

a deep crimson-red. Madeleine Davis is one of the most refined of the Japanese flowers, of fine form, the colour being a lovely pale rosy-heliotrope on a bluish ground. Chatsworth, in late flowers, was prettily striped rosy purple, in which state it is distinctly taking. Nina Dabbs is deep yellow with a greenish shade, Royal Standard being one of the best of the rich crimson sorts. The Wonderful, another of Tasmanian origin, with massive incurving petals, is not unlike the popular Mrs. C. W. Wheeler of a few years back; Miss Lallah Mirande is another large white flower, tinted heliotrope.

Incurved varieties calling for special notice are Mme. Ferlat and Mlle. Lucie Faure, both useful exhibition sorts. Decorative and market varieties are largely grown here and present a gorgeous display when massed in groups, as most of them are. Clinton Chalfont is one of the best market sorts, and although quite 5 feet high, should be useful for cutting. Tuxedo, a lovely orange-coloured bloom for December cutting, is invaluable, flowering freely and opening kindly. Frank Wilcox was noted for its bright bronzy crimson colouring. Gladys Roult is valued because of its neat medium-sized blossoms of pure white. Emily Silsbury, white; Eynsford White, still regarded as a useful white for market work; King of the Plumes; L. Canning, a good December white; Mme. Felix Perrin (syn., Framfield Pink), the best of the late-flowering rose-pink flowers; Mrs. J. Carter, a thread-petalled yellow flower; Mrs. Filkins and Silk Twist were also good. A capital batch of Anemone pompon Antonius was most striking. A pretty corner was seen in one of the houses, this being arranged with freely-flowered single varieties in a great variety of colours. For cutting they are unequalled and are deserving of extended culture. Those calling for special notice are Eucharis, a large pure white; Framfield Beauty, rich velvety crimson; Golden Star, Li Hung Chang, cherry-red on a golden yellow base; Rose Perfection, Mary Anderson, Miss Rose, and Annie Tweed, deep crimson.

Chrysanthemum Bonnie Dundee.—Apart from the value of this fine incurved variety for the exhibition board, it is equally useful for cutting. For specimen blooms, exhibitors know how constant it is, and noting last year its tendency to give a succession of side sprays, I determined to prove it as a bush plant, and it has given such a favourable account of itself, that to those who may not have treated it in the same way I would strongly recommend it. It is free in growth and flower, its colour bright, and, what is important in a decorative plant, its growth is rigid, supporting the blooms without any or very little need for stakes. In season it follows the well-known and justly popular Source d'Or, a variety that has held its own for such a long time.—S.

Popular show Chrysanthemums.—In looking over the records of the principal varieties in the leading classes at the best of the exhibitions, one cannot fail to be struck with the very small number of varieties that form the growers' stock upon which to rely for the strongest thirty-six or forty-eight best Japanese blooms. Out of twelve London and provincial shows, the most frequently exhibited blooms are the under-mentioned: John Seward, Australie, Mme. Gustave Henry, M. Pankoucke, Lady Byron, Mrs. G. W. Palmer, Mme. G. Bruant, Chas. Davis, Edwin Molyneux, Mutual Friend, Phebus, M. Océan de Leché, Edith Tabor, G. C. Schwabe, Cecena. Simplicity, Lady Hanham, Pride of Madford, Mme. Carnot, Robt. Powell, Ella Curtis, Mrs. J. Lewis, Mrs. H. Weeks, N.C.S. Jubilee, Viviani Morel, Dorothy Seward, Lady Ridgway, Mrs. C. Harman-Payne, Elthorne Beauty, and Pride of Exmouth. No doubt some of the others not named, but which are of undoubted merit, such, for example, as G. J. Warren, Mrs. W. Mease, President Nonin, Mary Molyneux, &c., have not yet had time to get into the hands of the general body of cultivators. It is also curious to notice that a very large number of fairly well known old

sorts have only been shown once out of the twelve opportunities thus afforded, and these varieties may be regarded as being gradually displaced by new-comers. The names of a few will suffice to show how fleeting is popular appreciation of show Chrysanthemums, for those only seen once at the shows referred to are Sunflower, President Borel, M. G. Biron, Milano, Reine d'Angleterre, Souvenir de Petit Ami, C. Shrimpton, Miss D. Shea, Mlle. M. A. de Galbert, W. Seward, Silver King, Duke of York, Etoile de Lyon, and several others less well known.—C. H. P.

CHRYSANTHEMUMS AT MAIDENHEAD.

THE Floral Nurseries, Castle Hill, Maidenhead, have been known for many years as the establishment over which the late Mr. R. Owen presided with so much credit to himself and so much appreciation on the part of those who are specially interested in the production of anything new or novel in Chrysanthemums. Mr. Owen's business is now conducted by his two sons, who seem to have inherited their father's love for the popular autumn flower. We called there a day or two ago, and were pleased to find that there were seven or eight greenhouses full of all the best of the season's novelties from various sources, home, colonial, and continental, besides large numbers of Messrs. Owen's own seedlings which are under trial, and from which it is safe to say there will be many interesting discoveries both in the incurved and Japanese sections.

These Maidenhead seedlings cannot be dealt with individually, because at present they are unnamed, but we were particularly struck with the purity of tone in several of the whites and yellows, to say nothing of the higher tones of colour such as the crimsons and purples, of which there was a goodly assortment. Of those that have been named, several have been exhibited with success and have been awarded first-class certificates, the last one being a very fine Japanese variety named Lord Cromer. It is of a rich velvety reddish crimson, with a golden reverse, and makes up a large bloom of great size. Mme. J. Tossal is a continental Japanese with very long, narrow florets twisted and curly at the tips; a hairy novelty of a pale lilac-mauve, with silvery pink reverse. Duke of Wellington belongs to the massive type of Japanese incurved; colour golden-bronze. In various parts of the establishment we came across the following, both being worthy of mention: W. Bardney, a large Japanese incurved with broad florets, of a velvety purple amaranth and silvery reverse, and Mrs. Philip Mann, a sport from Charles Davis, of a golden yellow shade flushed pale crimson. There were also some excellent examples of the big white Japanese, Mrs. H. Weeks, and several equally good ones of the deep yellow Carnot sport, called G. J. Warren. Close by is another rather striking-looking flower, named David Inglis, with medium-sized florets, colour deep crimson, with golden reverse. Lucine is a large white Japanese, very full and double, and Cameo, which is the next to attract our notice, is of a charming shade of pale flesh-pink, but belongs to the incurved type, and is a good, deep flower. In one corner stands a plant of Glory of the Pacific, a very free-flowering useful Japanese, not unlike the Christine family in form, but white, tinted lilac. This is regarded as a very useful variety for decoration or grouping.

Passing into another greenhouse where seedlings also abound are Mrs. Chas. Birch, a Japanese incurved, slightly hairy, pure glistening white; Glory of Maidenhead, a fine Japanese with flat florets of medium width, colour a peculiar shade of metallic crimson, reverse golden. The new Mary Molyneux, large pink; Mr. Chas. W. Cox, creamy white; Mrs. H. Perkins, also white; Mr. W. H. Grenfell, deep lilac-rose, are all more or less likely to attract the visitor's attention.

Among incurved, one of the most regular and perfect in form is C. S. Bates, a deeply-built flower of a pure golden chrome-yellow. In the

same section we noticed Pearl Palace, a good looking globular flower, deep and solid, colour pinkish lilac, and other flowers of fine form and good size, which are to be sent out as soon as they have been thoroughly tested and worthy of being named.

Returning to the Japanese section, we notice a few of continental origin, many of these being now past their best. Of those remaining there are some very large blooms of a new Japanese called Mme. Everard, with flat florets, white, tinted yellow in the centre; Mozart, also a Japanese of a very rich deep shade of golden yellow. The novelties introduced from Mr. Ernest Calvat are here in about the same condition as elsewhere, large, bold and effective varieties that meet with general approval. Fée du Champ-saur, a large white Japanese; Mme. Ed. Roger, the green novelty, and several more are good. Royal Standard, a dazzling crimson; Owen's Memorial, a crimson and gold Japanese of the Molyneux type, and Mrs. C. Herrin, white, are also noticeable.

NOTES AND QUESTIONS.

Chrysanthemum Golden Showers.—It is interesting to note that this curiosity secured an "award of merit" at the last meeting of the Royal Horticultural Society. The "merit" in this instance merely consists of a mass of thread-like florets drooping from the disc in an unkempt manner, and presenting no appearance of freshness, beauty, or general utility. It is only a curiosity.

Chrysanthemums—**Anemone** - flowered pompons.—Few Chrysanthemums equal in beauty the Anemone pompons when grown in a free manner. I have now both Marie Stuart and its chaste creamy white sport Emily Rowbottom in fine flower. The plants were grown on freely all through the summer to the terminal buds, and these were only reduced slightly in number and just sufficiently to allow each blossom to develop without becoming crowded and misshapen.—C.

NOTES ON PEAS.

FOR flavour and cropping I prefer Earliest Marrow, Al, Champion Marrow, Autocrat, Peerless, Chelsonian, Duke of Albany, Ne Plus Ultra and Emperor of the Marrows. The best early Peas I find are Extra Early, First and Best and Al; the best midseason, Dwarf Defiance, Main-crop, Criterion, Peerless and Champion Marrow. For late autumn I like Autocrat, Chelsonian, Ne Plus Ultra and Emperor of the Marrows. For an autumn supply I sow up to the third or fourth week in June.—WM. WHITAKER, *Creve Hall, Creve*.

The best Peas for cropping and flavour are Sutton's Early Giant, May Queen, Telegraph, Telephone, Duke of Albany, Dickson's Champion Marrowfat and Magnum Bonum. Eureka, Autocrat, Ne Plus Ultra and Sutton's Late Queen are among the very best. I consider Early Giant the best early Pea I have yet grown. Magnum Bonum and Eureka are the best for mid-season, with Autocrat, Ne Plus Ultra and Late Queen for autumn supply. The best time I find for sowing late Peas in this garden is the first week in June.—WILSON PALLISER, *The Gardens, Norton Manor*.

I generally grow Exonian as a first early, following with Gradus and Prodigy, and for mid-season I sow nothing but Ne Plus Ultra, and by making successional sowings of the latter a good supply can be had into the late autumn. These varieties are in my opinion all that can be desired for a good supply of Peas. Autocrat I find a very good late Pea.—A. C. SMITH, *Eldonhall Gardens, Cumberland*.

The best Peas, new or old, up to now are Duke of Albany and Duchess. The best early I consider is Wm. Hurst, and the best midseason Duke of Albany and Duchess. For late supply I like Ne Plus Ultra and Prince of Wales sown the last week in June or the first week in July.—JOHN BENNETT, *Ravenscroft Hall, Cheshire*.

The best kinds of Peas for early work I consider are First and Best, Chelsea Gem, Sut-

ton's Seedling, Harbinger, followed by Duke of Albany, Eureka, Peerless Marrowfat, Satisfaction, Dickson's Maincrop, and for late work Autocrat and Late Queen. I gathered Peas from Autocrat well into October last year, and it was sown the first week in June. In the neighbourhood Wm. Hurst is grown very largely as a first early.—J. PROCTOR, *Chippinham Park Gardens, Soham*.

—Chelsea Gem, St. Osyth, Exonian, and Early Moin are the finest early Peas. For main crops I prefer Interest, Telephone, Sturdy, Majestic, Criterion, and Duke of Albany, and for late, Ne Plus Ultra, Chelsonian, Autocrat, and Sturdy. For latest use I grow Michaelmas. The best time to sow late Peas is from June 15 to June 30, but in very fine seasons they may be sown till July 15. I have sown Chelsea Gem as late as July 30 with success, but sown on or about June 15 there is no Pea to equal Michaelmas. I have picked very choice dishes long after Michaelmas Day.—W. A. COOK, *Compton Bassett, Wilts*.

—William I. is the Pea I prefer for early use. Autocrat, to my mind, is the best Pea I grow. Maclean's Best of All is the best for late use.—WILLIAM H. BANNISTER, *Cote House, Westbury-on-Trym*.

—Those who have to supply Peas every day and are sometimes at a loss to find room to sow them, should fight shy of some of the newer varieties which find favour on the exhibition table. My favourites are William I., Prince of Wales, and British Queen. I have this season grown Satisfaction, which is excellent in every way. British Queen is my favourite for autumn use. I sow it the third week in June.—J. CAMPBELL, *Mickleover Manor, Derby*.

I have grown more dwarf Peas the last few years, as I find I can get more from the same ground than from taller ones, with less trouble in sticking. They are more suitable for south borders, and cold winds do not hurt them so much. English Wonder is the best early dwarf here—a very good cropper, pods well filled, of good flavour. Chelsea Gem is not quite so early; the first pods do not fill so well as in English Wonder, but it continues bearing well for some time after English Wonder has done when both are sown together. Exonian is the best and most profitable of the tall, early sorts (3½ feet), having well-filled pods of good flavour. Sutton's Invincible is the best second early with me, coming in about a week earlier than Gradus, having good long pods well filled with large Peas of first-rate flavour. It grows only about 2 feet high. Gradus is a very fine Pea, about 3 feet high, somewhat similar to Invincible. Sutton's Peerless with me is even a better Pea than Gradus, very fine dark green pods, and Peas which fill well and are first rate in flavour. Autocrat and Omega are both excellent late Peas, and if kept well watered, will keep free from mildew. I sow the second week in June for latest, and they generally keep bearing until frost cuts them down. The above is a select list from a great number of varieties tried. Sharpe's Queen, Veitch's Perfection, Duchess of Albany, and Boston Unrivalled are all good.—J. LANSDELL, *Barkby Hall, Leicester*.

—Veitch's Earliest Marrow is the best Pea I have tried for cropping, flavour, green colour when cooked, and clean, hardy growth. Harbinger follows it closely, and is excellent for crop and flavour when cooked. Duke of Albany and Criterion are good second early Peas, followed by Veitch's Maincrop and Prodigy, which are excellent in every way. Autocrat and Veitch's Perfection are grand Peas for late use. The growth is strong and free from mildew, and the crop and quality all that anyone can desire. The old Yorkshire Hero is a grand Pea for a late supply in this district. I grow it without sticks, and the yield is abundant. I consider the Peas named the best of any I have tried in this district, and I have grown a great many sorts. Alderman is a good late Pea, and so is Sharpe's Queen, sown thinly and not staked.—JOHN CHINSEY, *Norill Court, Abingdon*.

—For early use, Exonian, Senator, and Gradus are the best. The last I find to have

very large pods containing eight to ten Peas of excellent flavour, and it is an abundant cropper. For midseason I find Telegraph, Telephone, Cul-verwell's Giant Marrow and Veitch's Autocrat the best, and for late use Ne Plus Ultra. I sow once a week until the first week in June. This gives a succession until the end of October in ordinary seasons. May and June sowings are always given well-manured trenches, and do not suffer from mildew.—EDWARD TATE, *Bulweres, Colinsburgh, Fiji, N.B.*

—The Peas I find do best with me for first crop, and taking into account cropping and flavour, are Sangster's No. 1 and Day's Early Sunrise. The best early Peas I consider Sangster's No. 1 and William I. The best midseason Peas are Dr. Maclean, The Duchess and Telephone. The best autumn Peas are Veitch's Perfection, and Ne Plus Ultra. I have grown many others, but find these have done best with me in the north. The best time to sow Peas for an autumn supply is about the first or second week of May, but a good deal depends on the season.—WM. MACKIE, *Dunbeath Castle Gardens, Wick*.

—The best Peas for cropping and flavour I consider are Early Giant, Ringleader, May Queen, Duke of Albany (the best of all Peas), Veitch's Perfection, Ne Plus Ultra, Reading Giant, and Autocrat. The best early Peas I find are Early Giant, Ringleader, May Queen and Chelsea Gem; the best midseason, Duke of Albany, Telegraph, Veitch's Perfection and Ne Plus Ultra; and the best late, Autocrat and Latest of All. I sow Peas for autumn supply the first week in June, the middle of June, and about the first week in July.—THOS. OSMAN, *Ottershaw Park Gardens, Chertsey*.

Nelson's Vanguard is an old variety, but I have not found anything to beat it. It produces an abundant crop, and the flavour is excellent. The best early Peas are Chelsea Gem and Nelson's Vanguard; the best midseason, Early Marrowfat, Dr. Maclean, and Duke of Albany; the best late kinds Ne Plus Ultra and Latest of All. I find by sowing Latest of All about the middle of June I can gather good Peas well into the autumn.—J. CHILCOTT, *Ampton Hall, Bury St. Edmunds, Suffolk*.

—The best Peas with me are First and Best, Chelsea Gem, Eureka, Autocrat, and Veitch's Perfection. My best early this year was Chelsea Gem, and the best midseason Autocrat. Veitch's Perfection sown on June 1, and a good early variety sown on June 10, generally provide the last pickings. Autocrat I have found to be the best all-round Pea for flavour, continuity, and mildew-resisting. I sow it in weekly successions from the middle of March till the middle of May.—THOS. WILSON, *Glamis Castle Gardens, Glamis, N.B.*

Taking into account cropping and flavour I have not found anything to equal Veitch's Perfection as a maincrop variety. American Wonder I grow for forcing, and William I. as the best early Pea in the open. Ne Plus Ultra is the best for late use. Walker's Perpetual Bearer is also a good late sort. About the beginning of June I consider the best time to sow for late autumn supply.—W. GRAY, *Woodstock Park, Inistiog, Kilkenny, Ireland*.

The earliest Pea with me is Chelsea Gem, but the most reliable is Earliest of All, a good cropper. For second early Veitch's Maincrop is a grand Pea and a good cropper. Dr. Maclean, Telegraph, Maclean's Wonderful, and Veitch's Perfection are all excellent. For late crops I prefer Autocrat, Stratagem, Champion of England, Maclean's Best of All, and Ne Plus Ultra. The end of June is the best time to sow for autumn picking.—M. MCINTYRE, *The Glen, Inverclichon, Peebles*.

—The following kinds I consider good, and they do well with me: Early Marrow and Exonian I grow for the earliest crop, both excellent croppers and of good flavour. The best mid-season Peas in my estimation are Main-crop, Criterion, Chelsonian and Goldfinder, all good croppers and of excellent flavour. The best kinds that I have found for the latest crop are Ne Plus

Ultra, Autocrat and St. Duthus. I prefer the two last named, as the taller growing kinds suffer so from the autumn gales, especially if at all exposed. I sow my latest Peas from June 20 to the first week in July. Two years ago I sowed on the 7th, and the yield was all that could be desired. Of course the season has a lot to do with it. Sometimes I gather good pods up to the end of October.—JAMES MAYNE, *Bicton Gardens, East Devon.*

— If I were confined to one kind of Pea it certainly would be the good old *Ne Plus Ultra*. I am aware that its great height is an objection in some gardens where sticks are a consideration, but against this must be placed its great cropping capacity, good qualities as regards flavour, and hardy constitution. There are so many fine Peas that it is difficult to mention the best half-dozen. I have, however, found the following to answer well here for several years past, and have discarded many of the more recent introductions in their favour. Dr. Maclean I stick to, and have found it most excellent in every way. This is more hardy, and can be sown at an earlier date than any other Marrow Pea I am acquainted with. *Prodigy* is a fine Pea, and follows Dr. Maclean. It is a fine Pea, a heavy cropper, of fine flavour, and hardy. This Pea should be better known. *Autocrat*, too well known to need further remarks, is a good Pea. *Duke of Albany*, to my mind, is the best flavoured Pea in existence. It certainly requires a genial season to bring out its good qualities. *Sharpe's Queen* is another fine Pea. *Veitch's Main-crop* is also a valuable Pea. Of late varieties I confine myself to two kinds, viz., *Ne Plus Ultra* and *Veitch's Perfection*; both are too well known to need further comments. *Chelsea Gem* is a valuable Pea for late autumn on account of its dwarf habit. Frames can be placed over it, and it will do well through October. June 20 is about the date I sow my latest Peas; in fact, it is useless to sow later than this date in this neighbourhood unless it be dwarf varieties, which can be protected by frames. The excessive moisture together with early frost brings on mildew and otherwise checks the filling of the pods.—THOMAS ARNOLD, *Cirencester House, Gloucester.*

ORCHIDS.

GROWING ORCHIDS IN LEAF-MOULD.

RESPECTING this interesting question, the remarks by Mr. Burbidge are well worthy of perusal. I was pleased to see that Mr. Burbidge did not do as many authorities are apt to—that is, say that because he saw Orchids doing well on the Continent when grown in leaf-soil they must necessarily do the same in this country. Before we depart from the beaten track with respect to composts for Orchids, there are several points that need consideration. The first, and undoubtedly the most important, is the length of time the plants have been grown in this country. It is a well-known fact that Orchids of all descriptions, especially those of an epiphytal character, make a fine growth and flower freely for a few seasons, no matter how they are treated with regard to compost. They seem to always push roots of greater strength than at any other time, and doubtless fresh, sweet leaf-soil would attract them, containing as it always does so much woody fibre. The question that arises is, Would the roots produced after a few years' growth in the Orchid house take so readily to the leaf-mould, and will they be as long-lived in this substance as they are in a compost that allows of a free ingress of air? Again, there are many Orchids that grow naturally in decaying material of this description, but what of those species—I think Mr. Burbidge has ere now told us of some—that

grow naturally not on the large trunks of trees where this *débris* collects, but on small twiggy branches? The roots of the latter could not be expected to push through cubic inches of more or less decayed leaf soil, and even supposing a strong individual plant did so, how would it fare when it came to the time for repotting? Would there be enough vigour stored in the plant to enable the roots to make a second attempt to push through what must be regarded as an unnatural roothold? I am personally of the opinion that they would not, and I think that Mr. Burbidge is quite right to advise growers to proceed with caution.

There is no doubt that a certain section of fleshy-rooted Orchids and others with a wiry root, like *Cœlogyne* and many of the *Lycastes*, like a proportion of nice sweet leaf soil mixed with other ingredients, but as a practical grower the absence of air theory does not commend itself to me in the least. Indeed, it seems to me that leaf-mould of good quality would allow far more air to pass than peat when this becomes in the least decomposed and close. From want of a better material we have been in the habit of using as a kind of buffer, so to speak, crocks, charcoal, and other hard material. If our continental friends have discovered a material through which air in sufficient volume for the need of Orchid roots can filter, they will have rendered a service to horticulture, for, as everyone knows, crocks are but a makeshift, and nothing like a regular state as regards moisture is possible where they are used. By all means then give the case a fair hearing, as Mr. Burbidge puts it. If there is anything in it, British Orchid growers will not be long in giving it a fair trial, and it will come into use; if it is but a fad, it will go the way of all such.

H. RICHARDS.

Cattleya labiata Lewisi.—Under this name an award of merit was given to a pretty variety of the old *C. labiata* some two years ago, and the same or a very similar kind I have noted flowering during the week. It has not the pure snowy white of the true albinos, but is certainly a good form, the sepals and petals of good substance, a purple blotch spreading over a considerable portion of the lip. The great variety of colour and form is one of the chief recommendations of *C. labiata*, in addition to which it is easily grown and free flowering.—H.

Lælia amanda.—The flowers of this species, or natural hybrid, are each about 5 inches across, pale rose on the sepals and petals, the lip lined with purple and yellow. It is not very frequently met with and should be more grown. In the usual *Cattleya* house temperature it does well, and the plants may be potted in peat and Moss when the growth is not too far advanced. This will usually be about April. Keep it well up to the light and water freely when well established. After flowering keep it dormant, but the growth must not shrivel. It is a native of Brazil, and was introduced by Mr. W. Bull.

Cœlogyne assamica.—The colour of this species is somewhat dull, but it is distinct. The sepals and petals are thin in texture, brownish, the lip marked with red. It is a native of Northern India, and was discovered by Dr. Wallich early in the present century, though probably not introduced until some years later. The plant thrives best in the intermediate house and likes a moist and airy atmosphere, with shade from bright sunshine. Rather large pots and a rough, open compost are necessary, and during the time growth is active a free supply of water is necessary. No drying off is necessary even in winter.

Calanthe Veitchi.—A handsome spike of this comes from "R. R.," the flowers very rich in colour and of good substance, showing the plant

has been well grown. It is not always wise to overgrow this *Calanthe*, as it is apt to lead to the troublesome black spotting so prevalent with this and similar plants. It should always be well ripened, so to speak, keeping the plants well apart and not syringing overhead during the later part of the season. As soon as the spikes appear at the side of the bulbs the water supply must be lessened and discontinued altogether as soon as the leaves fall.

Cypripedium Pitcherianum.—This is one of the elder hybrids and has never become very well known. Its parents are good forms of *C. Harrisianum* and *C. Spicerianum*. As regards cultivation, it is one of the most free in growth, though not particularly strong, and in an intermediate or *Cattleya* house temperature there will be no difficulty in getting plenty of flowers at a dull season. In habit and general appearance it most resembles *C. Harrisianum*, but the influence of *C. Spicerianum* is plainly apparent in the fine dorsal sepal, of which the median line is rich purple. It was raised in Mr. Norman Cookson's collection about 1889.

Cymbidium giganteum.—Though reputedly shy-flowering, no Orchid blooms with me with greater regularity than this, and the plants are now very handsome, with their long arching spikes of showy flowers. The brownish red stripes on the sepals give the flower a bright appearance, and these are effectively repeated on the lip. It is a healthy-growing, vigorous species, requiring a sound, substantial compost to do it well and plenty of root moisture all the year round. Equal parts of peat fibre, loam, and chopped Moss suit it well, and the growth will be strong enough in this without the addition of manures, artificial or otherwise. A moist atmosphere in a cool, shady house and plentiful light sprinkling of the foliage in hot weather suit *C. giganteum* well.—H. R.

Cochlioda vulcanica.—This pretty and bright flowering little species is none too plentiful, for it often gives a lively bit of colour to the house during a dull season and is sure to be admired. The flowers occur on short, erect spikes, are variable in size and rosy carmine in colour. It does well in the cool house, and owing to its dwarf habit should be placed as near the light as possible in baskets or suspended pans. For compost use peat and Moss, and avoid giving too much room, as in this way the plants are easily injured. Its treatment as to watering and general routine is very similar to that advised for the New Grenadan *Odontoglossums*, excepting that the time for repotting varies, and this operation is usually carried out some time in early spring. Its habitat is high up on the volcano of Tunguragua, in Ecuador, whence, and from other localities, it has occasionally been imported to this country since 1872.

Pleione humilis.—There are few more striking bits of colour than the labellum of this pretty little Orchid, which is now coming into flower. A description fails to convey an idea of the delicate gradations of purple and rose to white. The front is ornamented with a fringe of delicate white hairs, just behind which are deep amethyst-purple spots. The one fault of *Pleiones* is they lose their foliage before or as soon as the flowers open. But if grown in small pots this defect may be easily hidden by associating the plants when in bloom with a few small Ferns, such as *Adiantums* and small *Pterises*. In some cases growers have dibbled in small Ferns with the *Pleione* bulbs at planting time, but personally I do not care for this plan, as it fines the compost down too much. *P. humilis* is best grown at the cool end of an intermediate house, in a shady corner if possible, and should be repotted in equal parts of peat fibre, loam, and chopped Moss as soon as possible after the flowers are past. After the young roots have pushed freely into the new soil, water freely until the fresh pseudo-bulbs are complete and the flower-spikes pushing. It is a variable species, a native of Sikkim, Nepal, and the Khasia Hills.

FLOWER GARDEN.

A BORDER OF MICHAELMAS DAISIES.

The illustration shows a border of Michaelmas Daisies in our orchard, which has been specially effective this year. It faces north, and has consequently suffered less from drought than the rest of the garden. About fourteen varieties of Starworts were planted there in October, 1897, besides Oriental Poppies, border Carnations, and a few other hardy things. The photographs were taken when *A. Novae-Angliae roseus*, *ruber*, and *pulchellus*, *Novi-Belgii floribundus* and *levigatus*, *A. acris*, and *Amellus bessarabicus* were all at their best. Purity was nearly over, and *A. grandiflorus* and *multiflorus* hardly yet come out. The tall *Pyreth-*

soon obtainable. One thing, however, which has rendered this variety unpopular is its tendency to splitting. In some gardens this is so bad as to render the blooms practically useless. The splitting, however, seems to be less in sandy soil, as a nurseryman near Great Yarmouth has grown it largely and the blooms have split but little. The soil of his nursery is very sandy. When in good condition *Gloire de Nancy* is unsurpassed both for wreath and bouquet-making, the flowers being extra large and the colour pure. Were it not for this pod-splitting in some soils it would have no equal as a market variety. So many fine showy Carnations are scentless, that sweet-scented varieties, if good in other respects, seem much more valuable.—NORWICH.

Ornithogalum lacteum.—As shown by Mr. Bain, gardener to Sir Trevor Lawrence, at the last meeting of the Royal Horticultural Society, this is certainly one of the most useful of the

growing in an old Italian oil jar, both in magnificent bloom; together the contrast was delightful. The winter, however, killed the *Zauschneria*, but I mean to plant it again in soil of a bank with the same combination below. *Tropaeolum speciosum* also I had several times tried to grow, and failed in all situations till I got ground roots. These I planted in all sorts of situations, and they have all done well and flowered, especially where they had a wall to scramble over. What is called a hardy *Fuchsia*? When one sends for such, one gets red sorts in return, and yet I have seen large bushes in cottage gardens in Suffolk of the lighter sorts—*Rose of Castile*, I think, one is called.—H. D. PALMER, *Korris Van, Falmouth.*

GUNNERA MANICATA IN THE NORTH.

ALL lovers of Nature will thank you for your two recent charming illustrations of this fine plant.

Michaelmas Daisies in an orchard. From a photograph sent by Miss Minnie Kingsley, Bourne Orchard, Hertford.

rum uliginosum and *Rudbeckia Newmanii* also looked well among these.

MINNIE KINGSLEY.

Cactus Dahlias.—Mr. P. H. Mules in his list of these flowers includes some, such as *Lucius* and *Clown*, not yet in commerce. He omits several of singular beauty that are in commerce, and that next spring can be purchased at reasonable prices. Chas. Woodbridge, of almost perfect form, colour rich deep crimson, one of the very best; *Mary Service*, golden brown, shading off to heliotrope, a singularly lovely colour; *Alfred Vasey*, reddish ground, shaded amber and pink, very beautiful; *Harmony*, the very best of all the bronzy shaded varieties; *Britannia*, soft salmon-pink, very fine; and *A. J. Deal*, the best scarlet, and a great improvement on *Gloriosa* and *Juarez*, have been found in the best stands this year and have been wonderfully admired.—A. D.

Carnation Gloire de Nancy.—This large-flowering, sweet-smelling white Carnation has few rivals so far as freedom of flowering is concerned. It is also a vigorous grower, large plants being

genus. In general character and formation the plant resembles *O. pyramidale*, but the individual flowers are both larger and whiter. In fact, the blossoms are snow-white, quite devoid of the creamy tint suggested by the specific name. The inflorescence in the plants shown was of the uniform height of about 20 inches, which would be increased as the flowering extended to the tip of the closely pyramidal head. It is in the latter that a prolonged flowering may be looked for. As a pot plant it is certainly worth attention, and by growing two or more in a 6-inch pot, a good display would result. The drawback from this method is in the fact that, like *Tuberoses*, when planted in duplicate the plants rarely flower together. A better way, therefore, would be to grow the plants singly in 5-inch pots. The species is of easy culture and quite amenable to ordinary greenhouse treatment.

Plumbago Larpentæ.—I see in the last monthly part of THE GARDEN mention made of *Plumbago Larpentæ*. This has done well with me in my Suffolk garden, and has quite taken possession of a small dry rock garden, and is every September a beautiful sight. One year I had it and a large plant of *Zauschneria californica*

Most of your readers will admit that they are magnificent masses of foliage. There are few plants that produce more massive effects in less time than the *Gunneras*. A few of the giant *Tobaccos*, *Solanums*, *Rhubarbs* or the *Cow Parsnips* might yield yet even better results under stimulating conditions. But then how widely different are these from the *Gunneras*, and yet how seldom we meet with them. Two impressions, both wrong, have greatly restricted the growth of *Gunneras* in Britain—the one, that they were tender; the other, that they could only be grown to full size either in or close to water. Miss Pirie's single sentence on winter treatment and the county her fine plants hail from may do much to dispel the one. I have no doubt that far more *Gunneras* have perished from coddling and winter coverings than from cold. Neither is there any necessity to plant *Gunneras* in or close to water. They will thrive more or less as semi-aquatic plants, but grow stronger, finer still in any rich garden soil, such as may generally be found in old, rich kitchen gardens or in nests of leaf-mould, decayed roots of grasses, &c., such as may be met with ready to hand in most home woods. Miss Pirie

says emphatically of her plant it is growing in a garden and is not near water. As already said, the plant will thrive in any good garden soil rich in humus. The mere size of the leaves appeals for shelter from northern, eastern, or strong western gales. The plants cannot show to their best advantage or display their fine foliage untarnished in the teeth of our biting blasts. With the exercise of forethought, sheltered places, sunny and warm, in plenty may be found for Gunneras. I have never had their fine foliage burned by an excess of sunshine, though summer gales have at times greatly marred the beauty of their stately leaves. Some of the finest plants and groups of Gunneras I have ever seen were grown by my late friend Mr. Sheppard on the cliff on the banks of the Orwell at Wolverstone Park, near Ipswich. A tiny stream trickled past, forming a pool lower down the cliff, and here among Ferns and other fine-foliaged plants, thinly canopied with trees, the Gunneras found a home exactly to their liking. D. T. F.

BORDER POLYANTHUSES.

Few hardy flowers better repay liberal culture than the Polyanthus. Primroses may remain undisturbed for several years, and if the conditions are fairly suitable they will even increase in bloom-bearing capacity, individual specimens carrying half a hundred or more expanded flowers. Polyanthuses, on the contrary, quickly lose strength, except perhaps in exceptionally favourable soils, unless annually transplanted, and the blooms are deficient in those qualities which render this spring flower so ornamental. Probably the best way to ensure a good display of this fine hardy flower is to raise a batch of young plants annually. In growth, size and quality of bloom yearling plants are much superior to older ones, that is if they are given liberal culture from the time they begin to make their growth. Polyanthus seeds germinate with remarkable freedom if sown as soon as ripe. Where a considerable quantity of plants is required, the easiest way is to sow broadcast in a frame, so that the seedlings can remain therein until the following spring, where they can be sheltered from very inclement weather. If planted out in such a young stage of growth they are likely to be cast out of the ground during the winter by frost and worms. The shelter is of course not absolutely needful, but the young plants keep their foliage better and continue to make roots all through the winter when guarded against extremes of wet and cold. When the seed crop is plentiful I sow in the open ground, leaving the young plants to take their chance. It is, however, necessary to sow as soon as the seeds are ripe, which is usually at the beginning of August. Then they come up with great freedom and the seedlings have time to get a fair hold of the ground by winter, but if sowing is deferred until the end of the month, the seedlings are liable to be disturbed by frost and worms. The ground should be well worked and surfaced with an inch or two of fine soil. Sifted refuse from the potting bench is just the thing. If the weather is dry, I give the ground a good watering before applying the fine soil, so that there is but little difficulty in keeping the seed-bed in a uniform state of moisture until germination takes place, which will be in about a month from time of sowing. If I have spare lights, I cover with them until the young plants appear, and if not, mats have to be used, in which case more attention in the matter of watering is required. If the weather is dry, a watering now and then will help to bring the young plants along, so that by the close of the autumn they will have several nice leaves and roots some 2 inches long, which will sustain them during inclement weather later on.

Additional strength will be imparted if they are given some weak liquid manure two or three times after they commence to grow freely. In February a piece of ground should be prepared by roughly digging it, and about the middle of March this may be broken down, stirred, and made fine with the fork, adding a tolerably liberal dressing of rotten manure. A north aspect is the best, as the Polyanthus loves a cool and moist atmosphere, and if the young plants get an occasional watering in dry weather, they will make good progress all through the summer, and will yield a fine show of bloom the following spring. In late autumn they may be transplanted, and will make a fine show either in borders among other hardy things, or they may be used for giving an early show in beds on the grass which are to be filled later on with tender things. In order, however, to fully realise the wonderful beauty and great worth of the Polyanthus, the plants should be flowered where they get shelter from the strong sunshine which prevails in late spring as well as from drying easterly winds. In the enjoyment of such conditions the lovely shades of yellow, maroon, crimson, &c., which characterise a good strain of this hardy flower are intensified, the trusses are of greater size, and the flowers remain in perfection very much longer than when fully exposed to parching winds and hot sunshine. There can be nothing finer in the outdoor garden in late spring than a bed of giant-flowered Polyanthuses in full bloom, and as a shilling packet of seed will furnish several hundred plants, there can be no reason why the majority of gardens should not be beautified with this old garden favourite. As I remarked at the beginning of this article, the Polyanthus soon degenerates if left alone from year to year. In raising Polyanthuses from seed every year or so, one is sure now and then to obtain an extra good form which he would like to keep and increase. The great enemy of the Polyanthus is red spider, and in the warmer counties of this country the foliage is sure to be so much affected, that the greater portion will die away during the summer. About the middle of August the plants should be lifted and replanted in good free soil, giving them a thorough watering should the weather prove dry. In the course of two or three weeks new roots will form, and during September young leaves will push out, so that by the close of the autumn the plants will be well established. This annual lifting and replacing in sweet, well-enriched ground exercise a stimulating effect on the plants, without which they soon come into an enfeebled state and eventually disappear. J. C.

Bulbvet.

Lilium rubellum.—The appearance of a coloured plate of this beautiful Lily in a recent issue of THE GARDEN brings to my mind the fact that last year I received two bulbs of a Lily from a gentleman residing in South China. When received they were in a very shrivelled condition, and remained dormant for such a length of time afterwards that I almost despaired of their ever growing. However, they eventually both started into growth. The stems were rather slender, but this was, no doubt, owing to their having become so shrivelled during transit. They both flowered when about 2 feet in height, the colour of the flowers being a clear rich orange, and quite unlike that of any other variety of *Lilium* growing here, the flower itself being similar in form to that of *Lilium candidum*. Two good new bulbs have been formed, and the growing and flowering of these will be watched with the greatest interest next season, as will also those of *L. rubellum*. The same gentleman also sent seeds of a very pretty trailer or climber, which flowered in a

remarkably short space of time after being raised in stove-heat. The flowers were small and of the exact representation of a five-rayed star, and rich lake in colour. After searching through various botanical works, and at last consulting Nicholson's "Botanical Dictionary," I find it is very much like *Ipomoea Quamoclit*, as both plant and form of the flower answer to the description given of this plant therein. A Japanese gentleman, when looking round at the time the plant was in flower, informed me that it grew wild in Japan as well as in China, and was greatly delighted to see it growing in England. He gave me the name it was known under in his country, but could give me no English equivalent for it.—A. W.

NOTES AND QUESTIONS.—FLOWER.

Meconopsis nepalensis.—The large rosettes of this showy Poppy that will produce their flowering-spikes during the ensuing year constitute at the present time a most attractive feature; indeed, where grouped freely together, few hardy plants have a finer winter effect than this—an effect always enhanced by a recent shower of rain, the moisture being long retained on the plants.

Hemerocallis aurantiaca major.—Like "H. S." (p. 420), I have found this magnificent Day Lily slow in coming into flower after planting. In comparing experiences with a number of other growers of *H. aurantiaca major* I have formed a pretty general consensus of opinion regarding its shyness in flowering for some time after being obtained. The flowers are so fine, that one is well repaid for waiting, but it is, nevertheless, disappointing that they do not favour us sooner.—S. ARNOTT.

THE FOG.

ON Monday, November 14, the north of London was enveloped in one of the densest fogs I have ever experienced. Fortunately, it was not of long duration, otherwise the effect must have proved most disastrous. As it was, I find it has left its marks, the glass being covered with a thick coating of black greasy secretion, necessitating the whole being washed before any sunlight can penetrate. With fine-foliaged plants it is early to say what the results will be. I find that Eucalypti standing outside have all the appearance of having been scalded, and inside there is already some indication of the mischief. I find that it is desirable to keep the temperature as low as is consistent with the safety of the various plants, giving a little moisture, for in a dry, warm atmosphere the plants absorb the fog and the poisonous gases contained therein. One instance in particular I have noticed; this was with *Begonia Gloire de Lorraine*. In a cool house the plants dropped but few flowers, while in a house where there was more heat, and consequently a drier atmosphere, nearly the whole of the flowers dropped off. I have previously noticed that where a fairly moist atmosphere is maintained the effects of fog have been far less disastrous than where more heat and less moisture have been given. Ferns do not appear to suffer much unless the fog is of long duration, and then I think it is from want of daylight more than anything else, though in some instances I have seen some mischief done. Once, after a heavy fog of several days' duration, I found some which had all the appearance of having been scorched. These were chiefly such as might be expected to resist the fog best, *Cyrtotium falcatum*, *Polystichum capense*, and others of similar texture being among those that suffered most, while *Gymnogrammas* and all others with a hairy surface suffered the least. I once had a good batch of *Mignonette* which promised well for bloom in November, but after a few days' fog the flower-spikes all went blind, and instead of making further advance, lateral shoots were made, and these in time tried to flower, but suffered the same fate as the terminal spikes. After various trials I have quite given up trying to flower *Mignonette* within the reach of London fogs

during the winter, though in the country I have had it as good at Christmas as at midsummer.

II.

KITCHEN GARDEN.

TOMATO GRAFTED ON POTATO.

The two plants (Potato Pierremont Seedling and Tomato Perfection) were planted side by side in a 14-inch pot. After they had become established they were inarched in the usual way and allowed to remain for ten days, when I cut the Tomato root off, also the Potato top,

there are complaints of the plants decaying in the centre and running. The chief cause is earthing up too soon. Dryness at the roots of Celery fosters running and the crop is spoiled. I am now in the midst of earthing up the latest lot. This in the middle of November of course is somewhat unusual, but the seasons vary, and if I had done the work a month earlier, growth would have been arrested and the crop spoiled. I need Celery as late as possible. I have frequently kept it to the end of May, but to do this one must allow the growth to be fully matured and not cripple it by moulting up. I wish I was as fortunate as Mr. Tallaek as regards the maggot. My plants this year suffered much and the attack

make the best use of leaves in the garden, as they are most valuable for forcing and protecting also. Endive and Lettuce, I feel sure, in winter and early spring would do much better in leaf-mould than decayed manures. The latter are often wet, cold and sodden, whereas leaves are light and porous and soon get warm when the sun shines during the day.—S. M.

Wintering Potatoes. The very mild, open weather prevailing is already affecting Potato tubers, although kept fully exposed to light and air and as cold as possible. The exceeding dryness and warmth of the soil up to and beyond the time of lifting even late varieties are probably to some extent responsible for this rather early sprouting, and the mildness of the season is accelerating it. There is no other course, seeing that cold storage is in relation to seed Potatoes hardly practicable, but to give the tubers the very fullest exposure to light and air. When the light is abundant, shoots harden and seldom elongate. Growths of this nature often remain almost dormant for four or five months after they are an inch long. To remove them is to weaken the tuber growths, but to preserve them with all care possible is to fully utilise the tuber's strength. If the atmosphere in which seed Potatoes are kept is very dry, damping occasionally should be resorted to, but only sufficient to check shrinking, a trouble incidental to very dry stores. Where tubers are wintered in sheds, nothing is better for a floor than is one of soil, as that invariably emits some moisture. But sprouted tubers, when the stocks have been carefully preserved, necessitate later planting than is needful for tubers in an absolute condition of rest. A stout sprout on a tuber an inch long is often equivalent to three weeks' growth on a dormant tuber after planting. To keep tubers well in check the store should not only be very light and airy, but should have a temperature of about 40°, as in such state there is no inducement to premature growth. When, however, as now in November, the outside temperature reaches to 60°, it is difficult to find 40° only in any closed shed or store.—A. D.

Tomato grafted on a Potato. From a photograph sent by Messrs. Kent and Brydon, Darlington, Durham.

leaving the two plants growing as it might be one. There was a fair crop of Potatoes, and the Tomatoes were quite a good crop, but, unfortunately, some of the fruit had been gathered when I took the photograph.

WALTER BRYDON.

Earthing up Celery.—The note at p. 370 is most opportune, as many excellent crops have been ruined by premature earthing up. Mr. Tallaek in his note says that Celeries that were moulded up in the dry weather will be unsatisfactory. I fear this is often the case, as frequently

came when least expected—at the latter end of August.—G. W.

Lettuces grown in leaf-soil.—At p. 383 "J. C. T." notes the value of leaf-soil for growing winter Lettuces in. I know of nothing to equal it, as the lightness of the material, with abundant but not stagnant moisture, enables the tender plants to make a quick growth. During the last hot, dry summer months having a difficulty in keeping up a good supply of Lettuces, I, as a makeshift, sowed the seed on nearly decayed leaves. I never saw better results. The plants grew very large, and in a short time, the cool, light root-run being just the thing to promote growth. We do not

PROTECTING BROCCOLI.

At p. 371, "A. W." writes that owing to the poor growth of Broccoli many will be too small for heeling in to protect from frost. I have some poor breadths, while others are first-rate as regards size. This is most marked in soil not dug or manured for the crop, my failures being where the plants followed early Potatoes on land that had been dug to clear the crop. In firm land there are good breadths of Broccoli, and my soil—a light soil resting on gravel—being the reverse of "A. W.'s," I never experienced such a difficulty as I did this season in getting out the winter crops. As I grow a goodly quantity of early Strawberries, and only take one crop, the land is not in bad condition. I do not dig or manure for the green crops. This system of cropping has answered so well of late years that I have followed it for Broccoli, Kales, and a late lot of Brussels Sprouts. Drills are drawn for the Broccoli, and, grown thus, the plants need less moisture and do much better in bad seasons. Protection will be needed on account of the tender growth. The growth during the past month has been most marked. This is the reason I advocate following "A. W.'s" excellent advice. Early kinds, such as Superb Early White and a late lot of Veitch's Protecting, I do not heel over but well mould up. These take little harm, as even when heeled over the tender heads suffer if the weather is severe. But there can be no question as to the value of heeling over plants for the supply from February to June, doubtless the most critical time, as if the plants or stems are injured in midwinter the supply will fail at the season named. The earlier kinds do well if the leaves are brought together at the tops and tied over the heads, and if lifted may be placed close together in sheds or the shelter of a cold frame. This will give early material that should be made the most of. Heeling over later lots is worth doing,

and I have in very cold districts seen dry leaves placed over the plants in severe weather and the crop saved.
G. WYTHES.

MAY AND JUNE BROCCOLIS.

At p. 370, Mr. Crawford refers to successional Broccoli, and names some excellent kinds. It is a difficult matter to test varieties, as locality and soil will account for some difference in season. Among the earliest kinds Mr. Crawford notes the good qualities of Backhouse's Winter White. I am pleased to observe he has the same opinion of Snow's Winter White as I have. For years I have not been fortunate with this variety; some of the plants given good culture have turned in in March and even later, and in others the heads are not worth sending to table. For over twenty years I have grown Cattell's Eclipse for April supplies, and it is one of the hardest Broccoli for the season named. So far I have found none to take its place, so shall continue growing this old variety. My note more concerns those kinds which give the supply in May and early June. The latter date may be thought full late, and that Cauliflowers will then be plentiful, but I never find I have too many at the season named, and the Broccoli is much valued. Model is one of the best introductions of late years, as it is a distinct variety, and its dwarfness, hardiness, and good quality make it a most valuable kind. I can never keep Model after the middle of May in ordinary seasons, the soil being very light, but by lifting and placing under a wall it can be retarded for some weeks. Mr. Crawford includes Late Queen, which, like Model, is a dwarf variety and later than Model. This should find favour, as it bridges over the time between the last Broccoli and the earliest Cauliflowers. Even the latest kinds fail to come in at the time needed in May or June if sown too early. I sow Model in May and Late Queen and Monarch the first week in June, as it is much better to have a sturdy plant than a leggy one. In cold, heavy soils my advice as regards dates would not be applicable, and the cultivator would need to sow in time to secure a good plant. I have included Monarch in my list of June varieties, as in early seasons I have had the Queen all cut by the end of May, and the one named is well worth growing. Some years ago it was sent me for trial, and I have always grown it since. It is a larger variety than the Model or Late Queen, and very late, which makes it doubly valuable. Mr. Crawford does not include this in his list of kinds, but it is a favourite in the north on account of its hardiness and lateness.

Doubtless there are other kinds market growers have of their own selection, but in the markets in this part of the country there is a great falling-off in the supplies after the early part of May. Large growers do not appear to favour the latest varieties, as doubtless the early Cabbage crop pushes the Broccoli on one side, but in private gardens there must be variety, and the Broccoli is always valued as green vegetables are none too plentiful at that season. May Queen is mentioned in the note referred to. Doubtless it is not unlike the Late Queen as regards lateness and quality.

G. WYTHES.

Round Potatoes.—I see by "A. D.'s" note on round Potatoes (p. 369) that he considers Reading Russet still one of the best red round Potatoes, and I am of the same opinion. The only thing is that in wet seasons disease is liable to attack it badly unless the soil is well drained

and light. It does particularly well in some gardens in Scotland. A gentleman residing in Argyshire tells me it does better than any other sort in his district. One thing is certain, when in good condition there is not a more floury, better-flavoured Potato. Its usual size is medium, the best for the dining-room. In some quarters the white round variety Renown has gained favour, which it justly deserves, as I consider it one of the best and most reliable Potatoes introduced of late years. It is handsome in form, a mealy cooker, and abundant yielder even under field culture.—C.

Parsnips in winter.—There are various ways of protecting Parsnips from severe frosts so as to be able to get at them with ease if the open garden should be frozen hard or covered with deep snow. Some lift a quantity of roots and lay them in soil in the root shed or an ordinary out building, but the loss of moisture from the soil and exposure to draught are apt to cause the roots to shrivel and consequently lose much of their flavour. After trying various ways, I do not think there is a better plan than lifting the whole of the roots and laying them in soil, crown upwards, in a sheltered corner in the open garden, having some Bracken in readiness in case of sharp weather. The roots can then be easily got at, and in mild weather the covering removed. In this way they will keep sound and retain their flavour quite as well as if left in their growing quarters, and the ground occupied by the crop can be turned up to the weather early in the winter.—J. C.

Protecting young Cauliflower plants.—The only certain way of saving young autumn-raised Cauliflower plants through the winter is by giving frame protection. Still, if the winter is not too severe, plants will often pass through it uninjured in the seed-beds and prove very useful for early transplanting in spring. Besides pricking out the usual complement into frames in October, it is a good plan to put out a few under the shelter of a wall in some cosy nook in the same way that Cos Lettuces are treated, so that if needed some protection can be given. If a few dry leaves are placed over the plants in severe weather, they will take no harm with 10° or 12° of frost, and more still if the ground is not in a saturated condition. A better way, perhaps, of protecting these open-air plants is to insert a few stout sprigs amongst them, and then lightly shake some Bracken over them. When such plants survive the winter and are well watered previous to lifting in spring, they often turn in better and are less liable to button than frame-protected plants, as they feel the check of removal less.—NORWICH.

Brussels Sprouts.—Although the quarters devoted to this crop had no special attention, the produce is remarkably good this season, and this notwithstanding the drought. The little button-like sprouts from the lower parts of the stems are of that nice nutty flavour so much appreciated, although even yet the tops are quite blue from the drought. I rely principally upon the Exhibition strain, and like it well. The growth is not so large as that of some others, but it is hard and stands the winter well, giving a long succession of sprouts of the best quality. At Livermere recently I noted some very fine heads of Paragon, a useful kind evidently. It is a good kind either for home use or exhibition. This crop is a considerable time on the ground, but it is one of the most useful of the Brassicas. For the main-crop I sow in the open air at the end of March, and as soon as possible prick out the seedlings 4 inches apart on firmly-trodden soil. They are set out 30 inches apart both ways, and always on undug ground, this necessitating a good deal of work when the soil is hard and dry, and also in watering until they get hold, but once they make a move, growth is strong and hard, and able to withstand the most severe weather of most winters.—H. R.

Autumn planting of Potatoes.—It is surprising to find, in spite of the well-known experi-

ence of Potato growers for generations to the contrary, that some persons still plant Potato tubers in the autumn. The most tangible reason for so doing was given me recently by a gentleman, who said that he did so now because he had less time for doing so in the spring. That is hardly a sufficient reason for doing with tender roots or tubers what common experience has proved to be undesirable practice. Certainly it does occasionally happen that tubers left in the soil all the winter make very good growth the following season, and if left alone produce very good crops. But then we see in such case only those which pass the ordeal successfully and know nothing of the many that may have rotted in the ground or have been eaten by grubs or wireworms, or have had their tops destroyed by frosts in the spring. If tubers be left in the soil very deep they may escape freezing and be late in pushing tops the next year. But deep planting is productive of weakness, because the shoots have to elongate in a blanched form so materially ere they can begin to obtain chlorophyll or make leafage. But never yet has it been shown that with the most favourable conditions have autumn-planted tubers, which can but lie dormant in the ground as they would if in a dry store, proved to be more productive than have good sets properly spring-planted. In the latter case also, if not planted too early, always attended with much risk, the tubers are safe and the plants come to no injury from spring frosts.—A. D.

LATE RIPENING OF SEAKALE.

OFTEN Seakale gives trouble by starting slowly when taken up in the early autumn for forcing in the Mushroom house, and I predict that this will be experienced again this winter. With a view to getting an early maturity in a portion of the crop, I planted some on a south border in the beginning of the season, and, strange as it may seem, the plants occupying the warmer site are later in ripening than the main crop, which has a less open position. This is so pronounced that I have had to draw on the batch intended for later forcing for the earliest cutting. There has been a growth about equal in strength of leaf during the summer. I should have considered the cooler site more favourable for a continuous and steady growth during the prolonged period of summer drought, this being attended with a corresponding early ripening of the crowns and foliage. This inconvenient trait in Seakale, however, must not be taken as an indication for future plantings, because the season has had such an unfavourable bearing on many other vegetables this year. It is only another instance proving how easily one's plans may be upset, and this more particularly when artificial watering is not a provision of the garden. Until the leaves have separated from the crowns it is not advisable to lift Seakale in any quantity for early forcing, because, unless subjected to a fairly brisk heat, it will remain unremoved for a long time. While lateness in Seakale is so predominant a feature, Rhubarb seemed distinctly earlier than usual. The late autumn rain extended the growth of the Seakale no doubt, but it was too late to excite a suspicion of growth in the Rhubarb, this because the soil was dry to a great depth and the rainfall too slight to penetrate to the roots. Seakale will be in greater request this winter than for some time past judging by the shortness of supply almost everywhere of outdoor vegetables. W. S.

Vegetables at Bristol.—At the late Bristol Chrysanthemum show vegetables made a surprising display, especially when the adverse season is taken into account. In the several classes in which liberal prizes are offered there was quite a spirited competition, and although so numerous, there was scarcely a faulty dish to be found among them. There were, in spite of caterpillars, some fine Cauliflowers, Carrots, and Parsnips, models in shape and size; Potatoes perfect in shape and free from blemish of any kind. Brussels Sprouts were not so fine as is generally the case,

which is easily accounted for. Some very fine Onions were staged in one collection, and in another equally good Leeks.—W. S.

Sowing seeds in heavy soils.—A common mistake with those having a heavy retentive soil to deal with is the desire to sow vegetable seeds very early in the new year. This more often than not leads to disappointment, especially after a wet or snowy winter. Such things as Peas only lie dormant, many often rotting, or if they come through the ground, remain in a stunted condition. The blame often falls on the seedsman, when the seed may have been perfectly sound and good. Where these cold, backward borders cannot be converted into warmer and earlier ones by incorporating a sufficient bulk of light leafy, open compost, much may be done to admit of earlier sowing with safety by first turning up the soil in October or November, digging deeply, and leaving the plot in sharp ridges till say March. Then if the weather is open, select so many of the ridges at equal distances, levelling the intermediate ones. Flatten those left so as to leave them some 3 inches above the ordinary level, draw shallow drills in these, sow the Peas, and fill in with a light, somewhat leafy soil.—J. C.

LEEKS SOWN IN AUTUMN AND WINTER

I AM not an admirer of very large Leeks, as when cost of culture is considered and labour is at all scarce the huge Leeks are not at all profitable. Excellent produce may be secured by sowing at any time from now till January. I notice in the majority of market gardens the Leeks this year are mostly small, as owing to late sowing—that is, in March—and the hot, dry weather following the plants in many cases were not planted till August, some even later. They then made slow growth and are not at all strong. The Leek is perfectly hardy in a young state, and though I would not advise sowing in heavy clay soil at this late period, it would be advisable to sow earlier and make the soil good for the seedlings. There may be many who can afford frames or shelter of some kind, and others who do not need large quantities may with advantage sow in boxes and obtain sufficient plants for their purpose. I do not advise sowing this vegetable under glass, as if Leeks are in well drained soil on an open border they winter well. Grown thus, they lift well at the end of April or early in May and will then give much less trouble than spring-sown plants, as in dry seasons the growth is too far advanced to be injured. Leeks blanched 6 inches to 8 inches in length are a useful size for the table. These served up on toast are a delicious vegetable, and one good earthing up early in the autumn will suffice to get the length of blanched stem necessary. The value of this vegetable is its hardness, as Leeks may be had in season from October to April, a period of six months, and at so small a cost they are among the most useful green vegetables we can grow; indeed, no other green vegetable remains sound so long or fit for table without loss of flavour. Thin sowing is a necessity, as it should be borne in mind the plants occupy the seed-bed a long time.

S. M.

Planting winter greens.—In the gardens of Lake House, Byfleet, I was shown the difference between winter greens planted with an iron bar and those set out in the usual manner. Mr. Bradley, the gardener, told me that in planting with a bar the holes were filled with water, no more being given afterwards. Certainly the difference between the two lots was very marked, those set out in the usual manner looking blue and stunted, whilst the more deeply planted ones had made a nice free growth.—J. C. B.

Forcing French Beans.—Except in gardens where there are very light and well heated structures, the forcing of Beans is not very remunerative during the duller months of the winter, and

only where the requirements of a large establishment demand it is such forcing worth the trouble. Their cropping powers are so small compared with the later spring growth, that to produce a regular supply in only small gatherings needs frequent sowing, and a goodly number of pots or boxes in each batch. Like Mr. Crawford, I believe strongly in shallow boxes for these as well as other plants, as I find they grow better in them, especially during winter than in deeper boxes or large pots. The old-fashioned plan of top-dressing forced Beans in large pots is a thing of the past. It often does more harm than good by damaging the leaves and stems and misleading those who are responsible for their care in watering. For first crops the dwarf-growing forcing sorts are preferable to the taller ones; their pods are small, it is true, but they are borne freely, and but little trouble is experienced in staking. Small pots are successfully adopted by some gardeners; with others they are not. Very much depends on local circumstances and the skill of the attendant. Seven-inch or 8 inch pots are better, and shallow boxes equal to either. It is important for first crops to sow new seed; loss of time and general dissatisfaction come from old seed that produces such irregular batches of plants, and Beans do not, only under exceptional conditions, retain their vitality over a long period. At Marston I noticed recently a very healthy batch of Beans in 8-inch pots.—W. S.

POGGIO GUERARDO, FLORENCE.

I HAD been lamenting that I could find no gardens here after my mind, and that churches, statues, palaces—though so supremely beautiful in themselves—altogether hold the field, when I chanced to hear from a young man who resides in the neighbourhood that one of the sights of Italy (that was the expression he used) was not far off, and if I could only see it I should be delighted with it in no common degree. That was sufficient to make me decide on the course to be pursued, and it was not long before my wife and I found ourselves on the Poggio Gherardo and asking for admittance at the door of Mr. and Mrs. Ross. That was at once granted to us in the kindest possible manner, and a feast of good things was soon spread out before our eyes. Mr. Ross is in the strictest sense of the words an Orchid grower. I have very often heard it said that if you grow Orchids at all you will soon come to think of nothing besides; they transport you, they fill you, they delight you so much, that there is no room left in your mind for anything else in the way of flowers, and certainly it is often the case. I have seen it over and over again. Mr. Ross's houses and collection of Orchids are splendid, and no connoisseur can tear himself away from them till a very long visit has been paid. Unfortunately, the Orchids were rather lost upon me, because, though I admire them very much, they are somewhat over my head. I have never had the opportunity of taking to them at all as I wish had been the case. But under Mrs. Ross's superintendence I had a delightful time in the place. The full Orchid season has, of course, not come on as yet, but the following grand plants were in blossom among many others that might be named: *Calanthes* of many varieties, among them the beautiful *Darabayana*; *Lelia anceps* and *L. autumnalis*, *Paphinia cristata*, some very fine varieties of *Oncidium Papilio*, *Cirrhopetalum ornatissimum*, *Dendrobium Pinalopsis*, *D. P. Schroderae*, *D. superbiens*, and many *Cypripediums*. There were several hundred young hybrid *Cypripediums* coming on and two of Mr. Ross's hybrids in blossom, *C. Rossianum* having four flowers, one stem being twin-flowered. Mrs. Ross told me

that frequently occurs. If I had seen nothing more than these it would have been a red-letter day to me. Though I do not think I should ever wish to grow Orchids to the exclusion of everything else, it may very readily be conceded that there is a fascination about them which cannot easily be surpassed.

As one so often finds about plants, the principle of compensation asserts itself on the Poggio Gherardo. Manifestly tropical Orchids have found a second home, which they like very much. I was told that cool Orchids do not thrive in the same way, and that some of the beautiful North American Orchids, *e.g.*, *Cypripedium spectabile*, resent any attention they may receive. This really seems to be only fair when for so many other things Nature does everything, and success is so easily gained. I may, perhaps, be allowed to say here that Mrs. Ross is an artist of the first rank, and she has made representations of all her husband's Orchids, which leave nothing to be desired. I think she has something like 1800 of these pictures, and we had the greatest pleasure in looking over a large number of them.

I have said that Mr. Ross is absorbed in the cultivation of Orchids, but Mrs. Ross has another department of her own, and she is very intent upon it. It is not for me to describe the mysteries of Vine growing and how Olives are graded in three several ways, &c. All this and many other things besides require an education of their own, and must be excessively interesting to those who are located in this sunny clime. My eyes very soon fell upon objects of interest with which I have to do in the Isle of Wight, and some two or three of them I shall venture to name. It is curious how one pounces on a thing with which he is familiar, and it seems as though he never could have enough of it. I was arrested at once by a large bed of Cushion Irises which were growing *ad libitum* on one of the terraces, and which looked as though they were conscious they had nothing in the way of winter to fear. If these in my garden were ever to have the same appearance on the seventh day of November, I should consider them doomed to most certain destruction before long. How such glorious foliage would be mauled by the bitter east wind! How the thick rhizomes of some of them would be overwhelmed by the floods of devastating rain! But here they were full of promise, which is not at all likely to be dashed, and a glorious feast of blossom may be counted on for a certainty in February or early in March. What would I not give for such a walk over the course! No need for any precaution about this or safeguard against that too probable danger. Iris *Susiana* and all the rest of them will never fail in Italy if you only give them a chance, and though I am here much too soon to see my favourite flower in all its beauty, I can well understand from the look of the plants that in point of size, as indeed about everything else, the blossoms must be of super-excellent value. Nerines are just now beyond their prime, but there were a few in blossom in pots, and it must have been splendid a short time ago to see a bed of Nerine *Fothergilli* at its best. Could anything of a more vivid colour be conceived? Among the many good things which I noticed in this garden, it may be said that I have never before seen *Dahlia imperialis* flourishing in the open ground; but I suppose this gives the difference between England and Italy. Here it is splendid and a very great ornament to the place. But my walk round the terraces and in and out of the different nooks must be left in great measure undescribed, or I shall call for too much space.

I think I may be doing some service to fruit growers in England, and specially to those who live in the south of it or in the Isle of Wight, if I recommend them to attend to the few following facts. I will relate as well as I can what I came across yesterday. We found ourselves in our peregrinations before a tree which I should guess to be 11 feet or 12 feet high, and I was informed that it came from Japan and rejoiced in the name of Kaki Giboushiu. This tree must have had at least 200 golden globes hanging from its branches, each one being nearly as large as a Jaffa Orange and of a glorious colour. When it was at its best it must have been a sight, and the tree must be well worthy of cultivation for the spectacle alone. But it is not as a spectacle that I am referring to it now. Mrs. Ross asked me if I had ever tasted the fruit, to which I confidently replied that I had done so. And how did you like it? was the next question she put to me. I said that is a different thing, and I do not remember that I was so much captivated by it. She then inquired in what way I had eaten it. I told her, and it seemed to amuse her very much, for she at once replied, it is no wonder that you do not care more for it: the idea of adding sugar to it is absurd, and no one ever takes it fresh from the tree—it sets your teeth on edge. I remember somewhere about twenty years ago that the late Sir W. Hutt brought Diospyros Kaki to Ryde, and Lady Hutt, knowing that I am interested in such things, sent me over the road a slice of the very earliest fruit, and with it the exact amount of pounded sugar, daintily wrapped up in a piece of paper, which she deemed to be necessary. Her kindness was indisputable, but her knowledge about the matter—and no wonder it was so at that time—was limited. Mrs. Ross laughs at the idea of sugar at all, and she says that when the fruit of Diospyros Kaki is eaten it should be treated in the same way as Medlars. At first it should be kept in some warm room, and it should not be eaten till it is transparent and soft. If you do this, she declares that it is well worthy of being called “the food of the gods,” and she thinks that in all her wide experience she has never come across anything that can be compared with it. Its flavour is unlike that of anything else; it is unique: it is “heavenly.” After such an attestation as this, it seemed well worth while to attend to any instructions regarding it, and the following two or three points may be noted. The best sort for an English garden is Kaki Giboushiu, because it comes on soon in the year, and therefore ripens better than some of the others; it is also of great size and of a beautiful colour. This Kaki is most avaricious of nutriment; it can hardly be too highly manured, and two good-sized baskets of sheep's manure are given to each tree in the course of a year. It is satisfactory to learn that this Japanese tree will stand at least 14° or 15° of frost, and Canon Ellacombe, I know, must have had it in his garden for well-nigh twenty years, but I am not sure if he is conversant with the points that have been emphasised above.

This imperfect notice of a very interesting spot must now come to an end. It is a delightful drive from Florence to Poggio Gherardo, and when you get there, the welcome at a stranger's hands makes you glad that the expedition was made. Boccaccio loved it, and described it in his “Decameron” under its old name of Palagio del Poggio as the first place visited by the company who fled from the plague in Florence, and his name will linger here through the days that are to come. Poggio

Gherardo was bought by Gherardo Gherardi in 1432, and till then it was called Palagio del Poggio. Mr. Ross bought it in 1889 from the last of the Gherardi family. It is said that Sir John Hawkwood besieged it and destroyed that part of the old castle which is not machicolated, and which is of far later date than the rest. The view of Florence, with its duomo and campanile, and all the surrounding tract of country, dotted over, as it is, by innumerable villas and bounded on the horizon by mountains which rise one above another, is a thing which can never be forgotten. It is a matter for thankfulness that Mr. Ross's castle and his Orchid houses were not ruined by the earthquake which was recently felt here with such tremendous force. As it was, I believe his loss in plants was very considerable, and his habitation has needed seventeen large iron clamps to hold it together since the shock. I have been several times told here that the leaders of science say that Florence would have been laid in ruins if the earthquake had lasted only two seconds longer, and that is the exact time which Mrs. Ross mentioned to me yesterday as standing between destruction and all their fair possessions in Italy.

Florence.

HENRY EWBANK.

VALUE OF WOOD ASHES.

THE value of wood ashes in gardens both for fruit and vegetable growing cannot be over-estimated, particularly where the soil is inclined to be heavy. They then not only act as a fertiliser, but also as valuable agents in raising the temperature of such soils, besides operating in a beneficial manner in keeping them open, and so rendering them more easily worked. On lighter soils wood ashes are also serviceable, only in a less degree, because the lighter the character of the staple the less need is there for their application generally, the exceptions being in cases where wireworm and maggot are troublesome and where the soil has become nothing but a mass of humus from repeated and heavy dressings of manure. This latter is often found to be the case where the soil is anything but light, and although the presence of so much humus is not then quite so detrimental, both in this and the former instance the soil would be greatly benefited by the application of a good dressing of wood ashes for a season or two in lieu of manure. These wood ashes, containing as they do a considerable amount of carbonate of potash—the quantity varying according to the materials used at the time of burning—sweeten humus-laden soils, so to speak, and counteract the evils arising from a too free use of organic manures. Again, the more charcoal the ashes contain the more is their value enhanced, as this takes up and retains moisture, which is thus stored ready, as it were, for absorption by the roots of both plants and trees, as the case may be, when they come into contact with it. On wireworm and maggot-infested soils wood ashes are of special value, as they greatly assist in getting rid of the troublesome pests if their application is steadily persisted in. They should then be applied as a surface-dressing at the time the seeds are sown in addition to giving the plot a good dressing when digging, taking care to incorporate them well with the staple. For sowing in Potato drills after the planting is finished and before closing in the drills they are of the utmost service and act as a first-rate fertiliser. For getting rid of fly on the seed beds of all the Brassica tribe nothing can equal wood ashes, only they must be applied in a dry state, while they can also be used on Turnips with similar effects.

The use of wood ashes in connection with fruit growing is also well known. Here they are valuable in many ways, but principally for incorporating with other constituents when forming new fruit tree borders. They are also used for mixing with new compost in the transplanting of fruit

trees when it is necessary to place some new soil over and round about the roots. As a surface-dressing for fruit tree borders wood ashes play an important part, as, in addition to their rendering valuable manurial aid, they also heighten the colour of the fruit. Again, they may be used with excellent effect in the pot culture of orchard house trees when mixed with other ingredients, also for Pines and Tomatoes. Wood ashes are also useful in the eradication of Moss on lawns.

A. W.

GARDEN FLORA.

PLATE 1199.

SOME NEW ROSES.

(WITH A COLOURED PLATE OF MME. JULES GROLEZ.*)

SEVERAL good novelties have been added to the existing large number of Roses during the last two years. Except in one or two instances there does not appear to be the same advance as was the case in bygone years when A. K. Williams, Marie Baumann, Catherine Mermet, Mrs. J. Laing, &c., were introduced, but then fashion has somewhat changed. Formerly show Roses were in most request, now the garden varieties are in demand.

Of recent novelties, Mme. Jules Grolez, the subject of the coloured plate, is one of the most beautiful. The purity and freshness of colour, the pointed outer petals, and the fragrance of the blossoms, combined with a vigorous constitution, proclaim this Rose as one of no ordinary merit. Perhaps the finest of recent introductions is the white Maman Cochet. Considering the popularity of the pink variety, a white form of the same Rose must command an equal, if not more abundant, share of admiration, especially from an exhibitor's point of view. Empress Alexandra of Russia is a great advance in Tea Roses. Its unique colour and splendid constitution will, I believe, place this variety in the foremost rank. L'Innocence is a Hybrid Tea of undoubted merit. A pure white Rose of the type of Kaiserin Augusta Victoria will indeed be most valuable. The flowers are of good size, borne erect upon good stiff stems—a desirable quality which florists will doubtless appreciate. Caroline Testout is one of its parents, and also of Mrs. Robert Garrett, which has good credentials from the States, and so far as seen here appears to be of a more brilliant pink than its parent. Aurora is another excellent Hybrid Tea, beautiful in form, free in growth, an abundant bloomer, and deliciously fragrant. Mrs. F. W. Sanford, if constant, must, of course, be good, for it is a pale bluish sport of that queen of Roses Mrs. John Laing. Other good novelties that are sure to retain a place in our collections are Mme. Cadeau-Ramey, Emilie Gonin, Jeanne Forgeot, perhaps the longest bud of any Rose; M. Ada Carmody, a lovely Cleopatra-like Tea; Mme. Eugene Bouillet, Rev. Alan Cheales, Robert Duncan, and Ferdinand Batel.

Among what may be termed garden Roses the most commendable are Mme. Rene Gerard, Frau Geheinnrath Von Boch, Souvenir de J. B. Guillor, Gruss an Teplitz, rivalling Fellenberg, and splendid for massing, and Perle des Rouges, the richest coloured dwarf Polyantha yet obtained. Two quaint, but interesting striped sports of Paul Neyron must not be forgotten. They are named Panachee de Bordeaux and Coquette Bordelaise. As a conservatory climber

* DRAWN FOR THE GARDEN at Gravetye Manor, Sussex, by H. G. Moon. Lithographed and printed by J. L. Goffart.

the climbing sport of Kaiserin Augusta Victoria will be valuable, and pillar Roses receive grand additions in Purity and Psyche.

Possibly there are other worthy novelties, for over sixty kinds were introduced during the last two years, but I prefer to have further acquaintance with them before I recommend them to readers of THE GARDEN.

PHILOMEL.

THE WEEK'S WORK.

KITCHEN GARDEN.

ROUTINE WORK.—Few gardens can be entirely devoted to vegetables, and with fruit trees near walks there will be tidying up to keep the quarters in a presentable state. Leaves and decaying matter should be removed and the ground made as neat as possible. Weeds still grow freely in spite of the near approach of Christmas, and these will need clearing away after hoeing, as we do not get sun now to kill them. All green crops are still growing freely, and I fear, should we get severe weather, they will suffer badly owing to their soft growth. It will now be advisable to heel over the Broccoli plants that are grown for late winter and spring supplies. The plants are still growing freely, but with December now in it is not safe to delay the work. I know many growers do not do this, thinking it best to leave the plants to chance, but the loss is great in severe winters. So far I have found nothing to equal the old plan of heeling the plants well over, that is, burying the stems up to the leaves and laying the heads to the north. This will check growth, and at the same time barden the plant and in a way prepare it for the change of weather. Late-planted green vegetables, such as Kales, Savoys, and Brussels Sprouts, will be benefited by having the soil drawn well up to the plants, as the portion of the stem close to the leaves is that most injured by frost. There will be a better return if the plants, previous to being earthed up, are divested of any yellow leaves, as these removed will allow of more earth being added. There should be no delay in finishing the earthing up of late Celery. Even the plants to give material for soups may have some soil to protect them. Leeks may likewise be moulded up to blanch the stems. Globe Artichokes should be cut over, the plants being then mulched with some protecting material. I find fine coal ashes the most effective, and in the autumn I remove some of the best side growths, placing these in boxes or pots in a cold frame. In case the older plants are injured, these give planting material in the early spring. Should frost not injure the older plants, I get a fine lot of later heads from the younger plants. Many growers place a goodly quantity of long litter round the plants in gardens where there are losses, but I do not think it the best plan, as the litter being wet does more harm than good. Dry leaves, ashes or Bracken I find the best. Jerusalem Artichokes will be best left in the soil and dug as required. Growth this year is much later than usual, and the tubers being softer will shrivel more quickly. In severe weather it is difficult to lift them with the soil in a frozen state. This may be met by placing long litter over a portion of the quarter. Failing this, a part may be lifted and covered with soil and litter. A final covering should be given Potato clamps in the open, as this will prevent excessive rainfall entering the clamps. Seed Potatoes of early varieties should be sorted and placed thinly in boxes or on shelves, going through those in cellars or rooms in bad weather. It will now be well to house pot Cauliflowers, as heavy rains will cause the plants to mildew badly. Affected plants should be dusted over with dry wood ashes and sulphur once a week.

CARDOONS.—It will not be safe to leave large full-grown plants in the open any longer, as though we have not had frost to injure the growths, the

heavy rainfall will cause the centre portion of the plant to decay. I have kept Cardoons for weeks after housing in a cool shed or root store, not exposing the blanched portion of the plant, but placing the roots in soil or sand. Cardoons may also be kept if suspended in a cool cellar with the roots intact, but I think treated thus they lose flavour and at times become tough if the store is at all dry. Later plants may be protected in their growing quarters. I have only this week earthed up the latest lot, owing to the late season. To protect these it will be necessary to give a covering of Bracken in severe weather. This is preferable to litter when procurable, as it is light and wards off frost efficiently. If plants are well blanched there is no gain in leaving them in the open. There is a great tendency to running this season, and such plants are of no value, being tough and flavourless.

WINTER TOMATOES.—There has been no lack of fruit up to the present. I have only just cleared out the late summer plants. More care will now be needed to keep the winter plants moving freely, fogs and damp, dark days being the greatest drawbacks to the winter fruiter. It is useless to think of setting any flowers that appear now; at least, such is my experience, as though of late years we have had winter fruiting Tomatoes sent out, they will not set in our variable climate—I mean from now to the turn of the year. With a little care one may finish up any fruits set. Insects are troublesome, the white fly being one of the worst to deal with, and strong doses of tobacco are not advised. If tobacco is used, it should be when the foliage is quite dry, fumigating several nights in succession in preference to giving one strong dose. The XL All is the safest, and one application will suffice in ordinary cases. Plants swelling their fruits should when watered get tepid liquid manure or other fertilisers. It will also be well to keep the fruits as near the light as possible. If the plants are still rooting freely, give a surface-dressing of light soil with spent manure, adding a small quantity of bone-meal. Any foliage not needed is best removed, as from this date all the energies of the plant should be centred on building up the crop that is swelling. Ripe fruits should be removed before they are quite matured. They will finish on shelves. A night temperature of 60° to 65° should be given in mild weather with a little air on the top ventilators to expel damp. A rise of 10° during the day will suffice with a free circulation of air. Plants for early spring fruiting should now be sparingly watered, and though it is necessary to keep them moving, it is well not to excite the plants. A shelf near the glass will be most suitable for them, and a temperature of quite 10° lower will suffice at night with 15° less by day than advised for plants in fruit. Those who rely upon plants from cuttings will find these need more care than seedlings.

DIGGING, TRENCHING AND MANURING LAND.—At this season of the year the grower will need to take every opportunity of preparing the land for future crops. The weather having been so open, many crops that would have been cleared are still green and giving some return. I never remember gathering French Beans in the open ground so near the end of the year. Vacant land should be given the food necessary, and in the case of elubbing with Brassicas it is of great importance to dress thoroughly at this time of year. When advising digging, trenching, and manuring it must not be understood I advise treating all soils alike. It would not be advisable in the case of heavy, wet, clay soil with the rainfall we are now getting to trench in the way advised for light soils. Earlier in the autumn I have found it well to dig such land, but not at this date, as if laid up roughly earlier the soil was in a workable condition, being dry, and would be pulverised by the exposure to the weather. In frosty weather such land may with advantage have manures spread over the surface or placed in heaps ready for digging in. Much good will follow trenching in soils that can be worked, keeping the good soil at the surface. In poor land or on a gravel sub-

soil bastard trenching is the safe method. This is digging two spits deep without changing the position of the surface and subsoil. If desired, the bottom may be dug or forked, but the food given should not be placed too low down; under the first spit will be deep enough. I have seen many failures by bringing up the poor, inert subsoil to the surface, and also by placing the food out of reach of shallow rooting plants. Now is the time to use lime freely, burnt soil in the shape of garden refuse and old soil. In the case of land that has been badly worked, lose no time in digging it to allow frosts to sweeten it. S. M.

FRUIT HOUSES.

FIGS IN POTS.—The first early batch of these, not necessarily a large one, should now be started if so long deferred. As I want them extra early, I have to start my trees correspondingly early. They are now showing signs of activity, the embryo fruits being on the move. These were started on November 1, or fourteen days later than the previous year, owing to a combination of circumstances beyond my control. My second lot of plants will be moved on gently as from December 1. Bottom-heat for those started on November 1 will be provided by about the same date too. Hitherto it was not convenient to arrange for it this season, and possibly it will be quite as well eventually that it was not so for the first month. From the time of starting these a night temperature of from 50° to 53°, with at times 55° when very mild, has been the rule, the increase during the day not being more than 10°, sometimes less. Now onwards I shall increase the temperature 3° at least during the next few weeks by night and from 10° to 15° by day, with a corresponding increase of atmospheric moisture. Up to the turn of days the bottom heat will not range beyond 70° and 75°, then when the leaf-growth is fairly on the move an increase will be given.

FIGS PLANTED OUT.—Unless for some years these have been started thus early, it is not expedient to make a move just yet, or if it be done, let it be gently. It is a question both of success and of succession. If the trees have passed their vigorous youth they are safer as regards holding their first crop, whilst the question of a succeeding crop has also to be taken into consideration. The fact of getting one crop in good time is creditable, but to continue with another requires a little more judgment and experience both to prevent an overlap and a break where great store is set upon the Fig for the dessert. Houses of moderate size are much better for successional crops than larger ones, although of course by having two or three varieties it is possible to get the desired succession. Before starting these permanent Figs, let both the trees and the houses themselves be thoroughly well cleansed. It is to be hoped that no mealy bug is in evidence. If it be so, strong measures must be resorted to for its extermination. For this purpose hot water is very penetrating, and so long as it can be used by means of a sponge without any discomfort to the fingers it is safe. This should be followed by a well-proven insecticide. Personally I have found the Chelsea blight insecticide to answer the purpose well by adhering to the printed instructions. Other and newer preparations are, I am fully aware, now upon the market, but it does not always follow that they are better. The only one of these latter that I would rank with that just named is the XL All. The object to be aimed at in all winter dressings is that of penetration. To accomplish this in the first instance warm water is the best, then, as just stated, follow with an insecticide, which will then have greater penetrating power. Beyond any question the labour now bestowed upon cleansing will bear abundant fruit later on when other work is pressing. Do not when attending to this work be content with merely washing the walls, for therein will be found comfortably lodged at times the insects of the future. Hot limewash is a great boon at this season, and if in its preparation a few handfuls of salt be

mixed, it will adhere far better to the walls. See that the Fig trees are not at all dry at the roots when started, but do not employ any stimulants now, unless it be a light dressing of bone-meal; rather wait till later on, when a better opinion of the necessities of the case can be formed. For instance, if the trees should perchance cast their first crop, then the previous application of any stimulant would afterwards encourage too luxuriant a growth.

LATE FIGS IN POTS.—These are still giving some nice fruits, but now the varieties from which the supply is being obtained is practically reduced to one, viz., Nebian or Grosse Verte. As a late Fig it is better than Negro Largo for extending the season to the furthest possible limit. It is, however, possible that when d'Agen is better known, that variety may be even later. This variety so far, however, appears to be little known. The fact is, these late Figs have not been brought into such prominent notice as they deserve, hence their special requirements have not been ascertained. When this is the case we shall probably find they are more in request than at present. The general stock of late Figs in pots, such as Negro Largo, which I still grow in the greatest numbers, Bourjassotte Grise and B. Noir, Col di Signora Bianca and Violette Sepor, have now all been repotted. For a few weeks past, since the last fruit was gathered, these trees have been standing in a house with sufficient heat in the pipes to maintain an average night temperature of 55°, with a fair amount of air during the day, which with the dry atmosphere has been conducive to ripening the wood. Before the end of the year these late kinds will be cooled down to the normal standard, and be allowed to rest until the end of March, or even later in the spring. Within the next few days they will be stood in the lateinery, from which the Grapes will have been cut by then. Thus the little warmth to mature the Vines and the Figs will be in unison. Non-attention to the proper maturing of the wood in the case of all late crops is a fertile source of failure. In potting these Figs the balls were lightly reduced, so that by employing pots one size larger a good amount of fresh soil could be added with the roots intermingled with it more than if potted minus the slight breaking of the ball, which, as a matter of course, loosened the roots. Later on, when cooled down, the pots of these Figs will be plunged in spent Mushroom bed manure until starting time comes round again.

EARLY POT VINES.—These have been kept, from force of circumstances, in the same house as the first early pot Figs, and although both will in a few days be transferred to the potinery proper (now occupied by the latest Figs), the early pot Figs will be lodged only for a few weeks until the first early Fig house is at liberty for its future occupants; hence the temperatures as given will apply in this case also. These early pot Vines are swelling their buds kindly, and when in a few days they are in more congenial quarters will no doubt make rapid progress. No bottom-heat has up to now been applied, but when moved, some dry leaves will be worked in amongst the pots, leaving the additional bottom-heat from piping turned off for a while longer. If too much excitement at the roots be afforded as compared with the top-heat, there is a possibility of an unequal break. So also will a high night temperature which comes near to the day standard. Those who have not as yet started their pot Vines will do well not to delay any longer. Ripe Grapes may even then be had early in May if desired. Note, however, that the temperatures do not rule higher than already indicated. If not dressed with styptic after pruning, let it be attended to at once, otherwise bleeding and consequent weakening will very likely ensue as the growth becomes excited.

FIRST EARLY PERMANENT VINES.—These, where they have been forced early in previous years, may now be started with safety, and if need be a week or so earlier than has been the wont if they are in good condition at the roots, not other-

wise. Allusion has been made previously to the watering of inside borders, but it will bear repeating. Do not be misled into the idea that the watering of inside borders is a matter of secondary importance—far from it. On the other hand, soak them thoroughly when well drained, seeing to it at the same time that the water penetrates in an equable manner. After this has been done, a top dressing of well-rotted farmyard manure may be applied, which will add its quota of moisture to the atmosphere, yet conserve that which is in the soil. HORTUS.

OCTOBER IN SOUTH DEVON.

DURING the past month 5.88 inches of rain have fallen on 18 days, against an average for the month of 4.15 inches, while the fall for October, 1897, was only 0.34 of an inch on 8 days. For the first 10 months of last year, however, the rainfall was 27.87 inches on 146 days, the average for the period being 27.38 inches, while during the present year only 19.84 inches have fallen on 114 days. We are, therefore, 7.54 inches behind the average 10 months' rainfall and 8.03 inches behind that of last year, wanting about 14½ inches in the next two months if we are to reach our yearly average by January 1. The greatest fall on one day was 1.31 inches, on the 16th. There have been 28 sunny days and 84 hours 40 minutes of sunshine, while in October, 1897, there were 97 hours 45 minutes, and the average for the month is 114 hours 25 minutes. The record for the first 10 months of the year has been a good one as far as sunshine is concerned, this having amounted to 1610 hours 30 minutes, in comparison with an average of 1593 hours 35 minutes, the record for the corresponding period of 1897, 1593 hours 20 minutes, being practically the same as the average. The mean temperature of the month has been 56.7°, against 54.2° for October, 1897, while the average for the month is 51.2°. The highest sun temperature was 112° on the 8th, the highest screen reading 68.9° on the 21st, the lowest screen reading 42.2° on the 2nd, while on the same date the mercury in the grass thermometer fell to 39.3°. The humidity of the month was 82 per cent., against 81 per cent. in October, 1897, and the ozone registered 44.2 per cent., ranging from 70 with a south-west wind to 20 with easterly wind. The total horizontal movement of the wind was 6450 miles, compared with 5590 miles in October, 1897. The highest daily run was 469 miles on the 22nd, and the greatest hourly velocity was attained between the hours of 9 and 10 a.m., when a rate of 30 miles an hour was recorded. On the morning of the 17th a terrific gust of wind, which tore off the roof of a house, blew in windows, and sent slates flying in the air a distance of 100 yards, was experienced in a well-populated valley. This disturbance was so local, that the anemometer at the observatory, scarcely more than a quarter of a mile away, did not register it. On the same day it was reported that the base of a waterspout, or a disturbance of the water caused by a whirlwind, was observed in the Channel from Teignmouth.

Although October has passed away, the tints of woodland and hedgerow give but little evidence of the waning of the year and the early advent of winter with its leafless branches. Only one month still remains to autumn, and as yet there are but few tints of yellow in the trees. Elms, Ashes, and Oaks in most cases are of an unbroken tint of green, and the Chestnut hard by, that generally is the first of all the valley to change colour, was, towards the end of the month, displaying much the same splendour of crimson and gold as it did last year in the closing days of August. It is true that there are leaves on the ground, and yellow leaves, but these lie chiefly in the Lime avenues, where the foliage has unmistakably assumed a paler hue, for the wooded hills show but few spots of lighter colour. Until well-nigh half the month was gone the swallows and martins were plentiful, but after the breaking of the heavy rains the majority of them disappeared. Iris stylata, that usually commences to

bloom in October, has not as yet unfolded a single flower-bud, nor has the giant Christmas Rose (*Helleborus altifolius*), though for the last three years it has been an October bloomer, expanding its first bloom on the 6th in 1895, on the 10th in 1896, and on the 23rd in 1897. Though the trees have retained the normal colour of their foliage so wonderfully, considering the abnormally dry weather that we have experienced during the past spring and summer, there is plenty of berried beauty in hedgerow and copse. The Gladwin's pods have already split and disclosed the yellow seeds within that will soon assume a brighter colour. The Sweet Brier hedge is studded with brilliant scarlet heps, and a crimson flush is seen on the Hawthorn hedges. In the shrubbery the Barberry bushes have been bright with vermilion fruit, the coral-pink berries of the Spindle Tree hang in clusters by the spinney walk, and many a Holly has its sprays thickly covered with its vividly coloured berries that gleam amid the dark foliage. Towards the end of the month the Ivy unclosed the blossoms of its rigid flower-clusters, burdening the atmosphere with heavy odour that attracted the semi-comatose wasps and bees, and in the intervals of sunshine filled the surrounding air with the monotone of multitudinous insect life.

In the garden the spires of the Acanthus have rendered an artistic effect, while *Achillea ptarmica* fl. pl. The Pearl continued its blossoming well into the month, and the white Japanese Anemones were in flower during the first fortnight, with the Belladonna Lilies standing in deep lines against the sheltering wall. Very valuable are these for indoor decoration, as they expand their blooms readily in water if cut when the lowest flower is just opening, their fine heads of pink-eyed blossoms, with their chocolate-coloured stems, being particularly effective in vases. The variety known as *Amaryllis blanda*, with a taller, less deeply hued stem and pale blush-tinted blossoms, with the extremities of the petals reflexed almost as much as in *Lilium longiflorum* and generally borne in greater numbers on the flower-scape, is exceedingly beautiful and quite as hardy as the type in the south-west. Of Asters a large number have been in bloom, *A. Amellus bessarabicus*, which commenced to flower in August, blooming throughout the entire month, and now, in November, in spite of the heavy rains that have fallen during the latter half of the month, bearing many sprays of perfect flowers. This Starwort is without a rival for the extended period through which its flowers are decorative, and should be found in every garden, its semi-dwarf habit and non-spreading characteristics rendering it suitable for borders of the most limited area. The pretty *A. cordifolius* and its variety *A. c. elegans*, with their branching sprays of small thickly-borne flowers, have been very ornamental both in the border and when utilised as cut flowers for the house, for which purpose *A. ericoides*, with its numberless minute Daisy-like blossoms, is always acceptable. The old-fashioned *A. diffusus horizontalis*, with its small maroon and white flowers borne on rigid branching stems, has been a favourite in cottage gardens for many a decade, but cannot compare for beauty with the great majority of the varieties now in cultivation. The white *A. polyphyllus* was a pretty sight at the commencement of the month, when the tall *A. puniceus pulcherrimus*, with its stiff flower-sprays thickly set with lavender-white blossoms, was very decorative. Of the Novi-Belgii section, Robert Parker, the most graceful in growth of all the Starworts, and invaluable for arranging in tall vases, was in full beauty early in the month, its large light mauve flowers, not too closely distributed on the sprays, being particularly pleasing both in colour and shape. Flora and Pluto are two dark-coloured varieties of merit belonging to the same section, while Archer-Hind, a late variety, with bright purple blue flowers borne in great profusion, is valuable both indoors and out. Of the Novae-Angliae section, Melpomene, the best of the purples, and ruber, the brightest of the reds, were blooming well early in the month, and towards its close *A. grandiflorus*, one of the

very best of the Starworts where it can be relied upon to flower before the advent of frost, presented a beautiful picture when swathed in the deep purple of its great golden-centred flowers. In all but the warmest localities this Aster should be grown in the sunniest position available and in light soil, as early ripening of the wood is desirable in order that the flower-crop may be perfected before frost sets in. The Begonias, though presenting a slightly less dense mass of colour, were bright throughout the month, while many of the large-flowered Cannas retained their gaudy bloom-spikes, and *Canna Ehmanni* iridiflora bore its pendent rose-pink blossoms. *Campanula carpatica* has been flowering sparsely, but the Marguerite Carnations and the early Chrysanthemums have been among the most effective occupants of the garden, the former, with their softly-coloured blossoms and the blue-green tint of their bountiful foliage, leaving a most harmonious impression on the mind, while the latter displayed a youthful vigour in the freshness of their but just-expanded blossoms of bronze, white, and gold. *Coreopsis grandiflora* has continued to bloom, though not with profuse abandon of its summer blossoming. *Cosmos bipinnatus*, from seeds sown in the open in the early summer, commenced to flower towards the end of the month, having in many cases reached a height considerably exceeding 6 feet. The plants need a certain amount of support during their growth, as they are easily twisted and broken by wind and rain. The foliage is very delicate, and large plants are especially ornamental, especially those of the white variety. Many specimens of *Crinum capense* have been in bloom, but became gradually less decorative as the month wore on. Dahlias have dowered the gardens with bright colour throughout the entire month, and the great golden stars of *Doronicum plantagineum excelsum* Harpur-Crewe have not been infrequent, while here and there a few late dwarf bloom-spikes of the Delphiniums were to be seen. The Mexican Daisy (*Erigeron mucronatus*) has remained in profuse bloom, and in some gardens *E. speciosus* still showed its mauve flowers. In the early days of the month the Coral Tree (*Erythrina crista-galli*) flaunted the relics of its long crimson flower-spikes, and great bushes of the hardy Fuchsia Riccartoni have not diminished the profusion of their blossoming. The Gentianella (*Gentiana acaulis*) has produced a sprinkling of its deep blue flowers, and a stray spot of scarlet marks the conclusion of *Geum coccineum* blossoming. *G. rivale* (the Water Aven), a little plant of which was introduced from a Devon orchard some three years ago, has spread in the wild garden until it has formed a patch a yard in diameter, which is scarcely ever flowerless. The Gaillardias, though still blooming, have considerably reduced the display of crimson and gold which they afforded earlier in the year; but the Everlasting Flowers (*Helichrysum*), stiff and formal as their blossoms are, were bright in some gardens at the opening of October. The heavy rain had a marvellous effect upon the great Hydrangea bushes, which, before its advent, presented a pitiable appearance with their drooping wilted leaves and flaccid-petalled blossoms, but after two days' downpour they took a fresh lease of life and beauty, remaining ornamental until the end of the month. *Hypericum Moserianum* has been in flower, and a few bright bloom-spikes of the Kniphofias remain in evidence, while the Lavateras still bear scattered blossoms of pink, white and crimson. *Lobelia fulgens*, though not providing such a blaze of vivid colour as it did during September, perfected many a later and shorter spire of vermilion blossoms, while *L. rosea* bore its softly-tinted flowers for the first fortnight of the month. The sweet-scented Tobacco plant (*Nicotiana affinis*) has preserved its beauty throughout the month, in the case of the later-sown seedlings, though its fragrance is not so apparent in October days as during the warm, dewy summer evenings. *Oxalis floribunda rosea* has been bright with blossom, and the Paris Daisies, white and yellow, are still producing

their simple flowers freely, while the Ivy-leaved Pelargoniums *Mme. Crousse* and *Souvenir de Charles Turner*, if not blooming with such prodigality as they displayed in past months, have borne many softly-tinted flower-trusses. It is too much to expect that the old plants will survive the coming winter in the open, as many that were left out last autumn did the preceding winter and thus presented large sheets of bloom when they attained the zenith of their beauty in the past summer. An occasional fugitive blossom has appeared on *Papaver pilosum*, and now and then the Welsh Poppies have borne a few pendent blooms of clear yellow. Pentstemons and herbaceous Phloxes flowered well into October, and the Winter Cherries, *Physalis Alkekengi* and the newer introduction *P. Franchetti*, with its much larger fruit-vessels, have created a brilliant effect with their glowing, orange-yellow calyces. *Phygelius capensis* was producing its scarlet flower-spikes during the early days of the month, when *Plumbago Larpentæ* was softly blue, and the Giant Ox-eye (*Pyrethrum uliginosum*) bore its slender-rayed white star-flowers. Of

ROSES,

the single white Macartney has bloomed uninterruptedly since early in July, and gives promise of continuing to expand its flowers should the present mild weather last. In this respect it is a great contrast to the rather larger single white Rose, *R. levigata*, which flowers before the Macartney Rose has commenced to expand its blooms, and is flowerless for the remainder of the year. The Tea Roses have provided a continuous supply of cut flowers, *Safrano*, growing against a wall, being without a rival in this respect, while *Mme. Lambert*, *Catherine Mermet*, and *Souvenir de la Malmaison* have helped to counterfeit the semblance of departed summer within the house. Against a cottage wall a climbing Rose has ascended to the roof, and beneath the eaves a dozen white blossoms hang. The China Roses have also yielded flowers, though not in any quantity, *Laurette Messimy*, *Irene Watts*, and *Queen Mab* being especially lovely in their colouring, in which tints of pink, rose, bronze, apricot, orange and yellow are delightfully blended. *Rudbeckia Newmani* has kept in bloom through the entire month, its deep orange, black-centred flowers being very effective and lasting in the border. *Salvia patens* has borne many secondary spikes of its deeply-blue flowers, which associate charmingly with the blossoms of the yellow Paris Daisy for floral arrangements which are to be viewed by daylight, while totally inadmissible under artificial light, which transforms the lovely blue of the flowers to black. *S. fulgens* and *S. coccinea* have also been blooming in the gardens during the past month, but as yet I have not seen the improved form, *S. fulgens grandiflora*, growing in the open. Late seedlings of *Scabiosa caucasica* have produced their beautiful light blue flowers, and the Winter Flag (*Schizostylis coccinea*) has commenced to unfold its crimson spikes of bloom. A tolerably light soil is best suited to the requirements of this plant, which in a heavy, damp staple often perishes. *Sedum Sieboldi* has borne its lilac-pink flower-heads above its glaucous foliage, and *Stokesia cyanea* has provided a deep note of colour in its purple blooms. The Winter Daffodil (*Sternbergia lutea*) has thrown up a profusion of its golden Crocus-like blossoms, which are very acceptable for indoor decoration. Arranged in wet sand when in an unexpanded state in a silver Algerian bowl, with appropriate leafage, they open well and produce an artistic effect. Early in October the perennial Sunflowers, *Helianthus rigidus* Miss Mellish and *H. leuciflorus* were golden with blossom, and the Jerusalem Artichoke (*Helianthus tuberosus*) has flowered abundantly in the market gardens, the bright yellow when seen in a good stretch having a striking effect. The blooms of *Tradescantia virginica*, though few in number at this season of the year, are conspicuous owing to their velvety purple colouring. The Violets have commenced to

bloom, but both those which have been transferred to frames and those that are growing in the open border have suffered much from the dry summer, where it was found impossible to water them copiously, and mostly show evidences of attacks of red spider, which parched soil and arid atmosphere are almost certain to engender. At this time last year the Violets, both double and single, were in profuse bloom. Now it is difficult to obtain a handful where a basketful might have been gathered then. The *Vuccas*, especially *V. gloriosa* and *V. pendula*, have been flowering with almost as great unanimity as did the *Dracenas* in the summer, spike after spike of ivory bells attracting attention. The Pampas Grass with its silvery plumes is now at its best, its shafts not having as yet been broken by violent gales. *Zauschneria californica*, which flowered well in September, retained its scarlet blossoms through the earlier part of the past month. Many late-sown annuals have also contributed their tints to the floral display of the month, such as the white *Antirrhinum*, *Salpiglossis*, *Cornflowers*, *Echscholtzias*, *Sweet Sultans*, *Phlox Drummondii*, *Marigolds*, and *Zinnias*; while of the common plants that grow where they list, *Centranthus ruber* and the yellow *Fumitory* (*Corydalis lutea*) have been in bloom. Owing to the lateness of the season, the Virginian Creeper had scarcely commenced to turn at the close of October; on some houses, indeed, the leaves of *Ampelopsis hederacea* and *A. Veitchi* were still wearing a green tint, unbroken by any suspicion of red, on the last day of the month. On others, the larger leaves had assumed a ruddy hue, while the smaller ones that clothed the outlying tendrils, which stretched like clinging fingers on the masonry, still wore their normal tint of green. On an ivied wall hangs a belated trail of *Clematis Jackmani*. *Clematis Vitalba* (the Old Man's Beard) has garlanded 20 feet of the height of a *Wellingtonia* with its feathery seed-vessels, which week by week assume a more silvery sheen. A *Cobea scandens*, that passed through the previous winter unscathed, has enveloped a cottage from ground-level to chimney in its rampant foliage, from which green mantle the great purple bell flowers, here and there, depend. The *Habrothamnus* is blooming against a sheltered wall, and in another garden the *Lapagerias*, red and white, are blossoming in a northern exposure. The Passion Flower is becoming every month more decorative, as the oval fruits assume a glowing orange tint and hang against the dark green of the leafage like fairy lamps. On some houses the Passion Flower is almost covered with these golden fruits. *Physanthus albens* has scaled some 20 feet of a cliff's face and has bloomed profusely in the summer, while now the great corrugated seed-pods hang from the wiry tendrils. Hard by, a fine specimen of *Plumbago capensis* has been hiding the green of its foliage beneath the pale blue of its bloom-clusters, and close by a vivid scarlet climbing variety of *Tropaeolum Lobbianum* has spread its flowering shoots over some 25 feet of the cliff's surface, and is painting it with brilliant colour. *T. tuberosum* is now at its best, and has mingled its orange-red blossoms with the white flower-clusters of *Solanum jasminoides* at a height of 15 feet from the ground. The *Solanum* itself is beautiful as ever in sheets of pendent white blooms. Some has had to be cut from above an upper window, so much did it exclude the light. There is no sign of a cessation of flowering, though it has now been blossoming uninterruptedly for more than six months, for the unopened bloom-clusters are as numerous as ever. The advent of frost will, however, peremptorily set a limit to its lengthened display.

Of the shrubs, the *Abelas* have been blooming sparsely. *Aralia spinosa* presents a variety of autumnal tints, ranging from deep orange to palest sulphur, while the leaves of the *Sumach* have assumed an almost ruby-red. The berries on the Strawberry Tree (*Benthamia fragifera*) are becoming ruddy in their colouring. *Caryopteris mustacanthus* was bearing its lavender-blue flowers at

the commencement of the month, when *Choisya ternata* produced a second crop of scented blossom and the shoots of *Cytisus fragrans* were studded with golden blossom. *Escallonia montevicensis* flowered until the middle of October, and the double Jew's Mallow (*Kerria japonica* fl.-pl.) bore its orange-coloured blossoms. The *Laurustinus* is commencing to whiten the maroon of its bloom-trusses, but the flowers of the *Leycesteria* have departed, nothing but the whorls of pendent purple bracts remaining. The Snowberry (*Symphoricarpos*) carries many a round white ball on its slender shoots, and the shrubby *Veronicas* are in good bloom. The standard *Magnolia grandiflora* has shown no diminution in the number of flowers it bears, though their individual size is somewhat less than in the warm summer days.

S. W. F.

STOVE AND GREENHOUSE.

CAMPANULA MIRABILIS.

VARIED and extensive as is the Bellflower family, it contains no species or variety that will bear comparison with the above novelty, which, so far as the British Isles is concerned, has this year flowered for the first time. From the descriptions received from those who had either flowered or seen the plant in bloom, it was reasonable to assume that the new-comer would prove as beautiful and useful as it was distinct. From the comparatively meagre present knowledge of the plant—introduced to commerce, I believe, through Herr Max Leichtlin, of Baden-Baden—it would appear rather more inclined to be a biennial than a perennial. It is, however, scarcely biennial, in so far as the plants flower in the second year and perish as a result of that flowering, because the actual blooming stage in at least two known instances has not been reached till the third year, the plants meanwhile proving quite hardy in the open. From the seedling stage growth is rather slow in the first year, but subsequently a singularly prostrate rosette of leaves close upon the ground is developed. The leaves forming the rosette are somewhat thick and fleshy, the lower ones spreading out to a diameter of about 9 inches or 12 inches, the succeeding leaves smaller and arranged in an overlapping manner, usually alternate with the older ones. In this way the fully-grown rosette, where liberal cultivation has been given, will reach nearly a foot across, and thus form quite a unique feature among Bellflowers generally. Another marked feature of the species is the semi-succulent character of the foliage, which is slightly toothed or notched and of a shining green.

In July last the plant received a first-class certificate from the Royal Horticultural Society. The plant, however, was a small one and in no wise bore out the descriptions that had preceded it. So far as can be determined, it is a plant that must have liberal treatment from the very first if justice is to be done. Furthermore, it would appear more essentially suited to grouping in the rock garden or for planting in the border in good soil. Having raised the seedlings and grown them to a size fit for planting out, this should be done at once and quite early in the year if possible, so that a season of growth may be given the plants before winter arrives. At a subsequent meeting of the Royal Horticultural Society a very fine plant was shown by Mr. M. Prichard, Christchurch, Hants. This example was a foot or more high and carried a splendid pyramid of pale blue flowers. These latter, though smaller, somewhat resemble a small Canterbury Bell without the collar. It is evidently a free-flowering and

graceful plant, the latter item scarcely conveyed in the accompanying illustration. The plant exhibited by Mr. Prichard was three years old, and I am now informed that a good crop of seed has been secured without being artificially fertilised. This fine example carried about 100 flowers, and though it is expected it will perish, one or two growths are at appearing the base. Another example that flowered at Christchurch had larger though fewer blooms. Up to and including the spring of the present year the seeds of this plant have not germinated freely, and only a very small percentage of plants has been raised. These,

the flowering, and even in the present year with abundant heat no greater progress has been apparent.

There are some good examples of this fine species at Kew, some of which should flower another year. The species is of Caucasian origin, though even here it is reported to occur in but very limited numbers—indeed, it has been said that but a solitary example was originally found. So far we have not the success in Britain that has attended the growing of the plant at Baden-Baden, where one example, I believe, is said to have produced a pyramid of nearly 200 flowers—a charming picture indeed,

Campanula mirabilis.

however, have so far submitted to good ordinary culture. Better results may be forthcoming when fresh home-saved seeds can be obtained. These should at least germinate more freely and be generally of a more reliable character than those that have been obtainable up to the present. As some slight variations have already occurred in the flowers of this plant, it may not be amiss for those who can give the needful time to raise seedlings in quantity in the hope of obtaining distinct shades of colour. Perhaps the chief drawback to the plant is the length of time taken from the seed sowing to

as the flowers are of a most pleasing character and the general habit quite unique. E. J.

Pinguicula caudata.—This pretty little plant is not so much grown as it deserves, for the little rosy flowers are produced over a long season and are very quaint and distinct. The culture of the plant is not difficult, but it is somewhat different from that of most greenhouse plants. It delights in a very moist atmosphere with plenty of fresh air, but draughts of cold wind must be avoided. The roots require care, and those plants that now seem inclined to go to

rest may have the water supply considerably reduced, though not entirely withheld. The safest time to repot is in spring, and at this time, too, any necessary division of the roots may take place. For compost, chopped Sphagnum Moss may be mixed with half its bulk of turfy loam and sand.

Pelargonium West Brighton Gem.—This variety is very largely grown in some cases for the flower garden, and fine it is for the purpose. It is also one of the very best of winter-flowering kinds, and a houseful of it at this time of year produces an immense quantity of spikes. So free is this kind, that the plants struck in boxes for the open air, though put in in August, will in most years be a blaze of colour by Christmas, and yet be as good as ever in the beds the ensuing season. It is, in fact, one of those excellent kinds of which we have too few. If grown specially for winter-flowering the cuttings may be struck at or before midsummer, potted singly into a 5-inch, or three into an 8-inch pot, and stopped three or four times, the bloom-spikes being kept pinched out until they are placed inside in September. The plants are useful for decoration right on until late spring, for if carefully attended to with a little good concentrated manure at the roots, they will keep dwarf and full of flower for six months.

CARNATIONS FOR PROFIT.

IN Mr. Iggulden's interesting notes on the above (*THE GARDEN*, p. 408) he refers to Primrose Day as being disappointing. He is not the first that I have heard make a similar remark, yet I think it will be a long time before we find a good yellow with a better constitution. The greatest fault with it is that when grown on from layers or cuttings the main shoot is apt to produce a large, over-full flower which bursts. Take a plant which has had the main stem taken out, and the side shoots will produce well-formed blooms with large petals. I find that several growers who had discarded it on account of the first flowers being too heavy and bursting the calyx have gone back to it again after seeing it under different conditions. I quite agree with Mr. Iggulden with regard to the value of Germania, yet I should certainly give the preference to Miss Eva Campbell. I have now grown this in pots for several seasons, and although it cannot be considered to belong to the winter-flowering section, it will bloom well early in the spring, and the blooms are certainly of the finest form and richest shade of yellow of any that I have seen. Mr. Iggulden refers to Winter Cheer as not being robust. I have had the same experience, but after obtaining new stock, I must say it keeps up its constitution well, and where it is done well it will require something very good to supplant it. Of crimsons I am pleased to hear that Duke of York is still in favour, yet I think if Countess of Warwick were tried beside it it would stand a very poor chance. The latter is a seedling from Winter Cheer crossed with pollen from Uriah Pike, and has the dwarf, free-flowering habit of the former with the rich crimson of the latter, and is sweet-scented.

So much depends upon the culture of Carnations, that I should not like to condemn any particular variety. I find that in most instances where they are grown for winter flowering the stock has a tendency to deteriorate, and it is only by growing a number of plants on during the summer in the open and selecting the most vigorous for cuttings in the autumn and winter that a healthy stock can be maintained. Perhaps the best results are obtained by planting out some young stock early in the spring and taking cuttings as early in the autumn as they can be obtained. It will be of no advantage to take them before the side shoots have made a good start. Strong, healthy cuttings well cared for form the groundwork of success in growing Carnations for profit.—A.

—On reading Mr. Iggulden's remarks on Carnations, I find that Miss Jolliffe is omitted from his list of profitable varieties. At this I am

rather surprised. I am aware it requires careful culture, but it well repays it, and I do not think there is any pink winter-flowering Carnation so free flowering. No doubt its propensity for dying suddenly without any apparent cause is against it, and the individual blooms are not so large as those of Thérèse Franco or Reginald Godfrey, but the quantity well-grown plants produce is astonishing and the colour rich. I remember seeing some years ago a quantity of Miss Jolliffe at Mr. Beckwith's nursery at Hoddesdon. The plants were in 6-inch pots and the picture of health, it being regarded by that firm as the most profitable pink variety grown. If a little disbudding is done the blooms come larger. The white variety Uncle John, named by Mr. Iggulden, I do not know, but I am wondering if he has ever given La Neige a trial. As with Miss Jolliffe, the blooms, if disbudding is not practised, are apt to be on the small side, but if the smaller buds which usually cluster around the terminal one are removed, a fair-sized bloom will result. As for a free much-branched habit of growth and free-flowering, I question if it has any equal. The flower-stems are also stiff, which is an advantage, as they are easily arranged. Cuttings of La Neige strike readily. As a scarlet, Alegatiere seems to be falling into disrepute; why, I know not, as the plant is vigorous, not liable to disease, and produces freely flowers of extra large size, not so dark in colour as Winter Cheer, but rich for all that. Now and then blooms come flaked with white, which I suppose is a drawback from a market grower's point of view.—B. S. N.

COSTUS IGNEUS.

THE individual flowers of this plant last but a short time, but they are produced with singular freedom, and, moreover, the flowering season extends over many months. Plants here that were in full bloom in August are still (November 18) very gay, while there are many flowers yet to open, as indicated by the swollen apices of the growths. The colour is a very rich bright orange, quite distinct from anything else in stove and greenhouse plants, and as each flower measures upwards of 3 inches across, the effect of these upon the handsome deep green foliage is very fine. There are various ways of growing *Costus igneus*, and perhaps the best way to ensure large plants and strong growth is to plant out the crowns in spring in a light position in a warm, moist house. Here they will throw up immense stems that produce a lot of flowers, but they would in most cases soon become too large for convenience. Very handsome specimens may be grown in 10-inch or 12-inch pots, in which sizes they push up stems about 18 inches high in great profusion, making a finely furnished plant, the outer stems almost hiding the pot, the centre ones rising highest, and all alike crowned with the beautiful blossoms. The compost may consist of equal parts of good loam and leaf-mould, with a plentiful addition of dried cow manure, or its equivalent in guano or some good fertiliser, and a dash of coarse silver sand. If the leaf soil is difficult to obtain, use something that will keep it light and porous, a little pounded charcoal being a suitable addition. The object is to get a quick, yet sound growth. If rushed on in too great heat and moisture the flowers will be few and of poor texture, but with moderate heat, judicious ventilation, ample light and a genial moisture, the growth will be solid, yet free, and abundance of blossom will follow.

When bringing on young specimens, a shift may be given about May or the beginning of June, but with larger plants that are given a good margin of pot room at first, the one potting suffices, and this should take place as soon as possible after the young shoots appear at the

base of the old stems. It is a very free grower, and for this reason somewhat frequent division of the plants is necessary. If left too long, the growths get crowded, and as there must necessarily be a limit to the size of pots used, they do not all get a fair amount of nutriment. When the pots are well filled with roots, occasional applications of liquid manure are essential, and weak doses of clear soot water have an excellent effect upon the colour of the foliage. The plants rest during the later winter months, and at this time do well in any comparatively cool, light house, requiring very little moisture and an occasional look over for decaying foliage. Thus it will be seen the culture of this plant is particularly simple, and it is so beautiful when well grown that it ought to be included in every collection of stove and greenhouse plants. It is a native of Bahia, whence it was introduced in 1882.

CALLA ELLIOTTIANA.

SOME few days ago I saw this fine plant growing by hundreds, all either with open flowers or showing spathes in an advanced stage. The sight was to me unique, as I do not remember ever having before seen a dozen plants in flower together. This plant has proved a difficult subject with most people, and so many conflicting statements as to its correct treatment have appeared, that it may be interesting to some readers of *THE GARDEN* if I give, in short, the main points of the treatment afforded to bring about the above results, and to turn what has been looked upon as a spring or early summer flowering plant, and a shy and uncertain one at that, into a free and still more useful winter-flowering plant, beautiful in all its aspects, whether in or out of bloom. Most of the plants were seedlings twenty-six months old, and flowering for the first time in 5-inch pots. The flowers were about two-thirds the size of the bloom shown in the coloured plate in *THE GARDEN* for November 24, 1894, and of a softer yellow colour. Other plants there were older than these which bore bigger flowers than that in the plate, but my interest centred mostly in the young plants, true models of good culture bearing *Caladium* like mottled leaves and fine for all purposes of indoor decoration.

The treatment given is to sow in stove heat some time in September (this year's seedlings were already from 3 inches to 4 inches high), grow on in this heat all winter, and when they show signs of ceasing growth, or as soon as it is safe to do so, remove them to an intermediate house, withholding water at the same time. Later on they are transferred to a cold frame and bated with all the sun-heat they can get. In this way they are kept dormant for about five months, then they are repotted into a good, porous, sandy mixture in which leaf-mould appears to form an important part, and replaced in heat to go through another season's growth after the same fashion. In October of the second year, or about twenty-five months from sowing the seeds, the plants begin to throw up their spathes, and they then flower on in succession for a long time. As said before, the flowers of the first crop are smaller individually than those on older plants, but they are none the less beautiful, and a batch of young plants such as I have here attempted to describe in full bloom is a revelation. J. C. TALLACK.

NOTES AND QUESTIONS.—STOVE.

Griffinia hyacinthina.—It is only rarely this striking plant is seen blooming freely in the greenhouse, though a fine spike of it is among the handsomest of bulbous flowering plants. Quite recently, however, some small examples were noted in flower at Kew, and, while not particularly strong in spike, had a good many buds as yet unopened. The deep mauve-violet tint in the divisions of the perianth is very remarkable in this plant.

Begonia Winter Cheer. This is the most cheerful looking of the series that as yet have resulted

from the crossing of *B. sacotrana* with the ordinary tuberous kinds. Of the former, however, there is but little evidence in the hybrids, which are but little removed in habit and flowering generally from the earlier types of the tuberous *Begonia*. If, however, the same rapid strides mark these later kinds as are now so apparent in the *Begonia* to-day, a few years hence will see many beautiful things.

TREES AND SHRUBS.

THE WHITE-STEMMED BRAMBLES.

(*RUBUS BIFLORUS*, &c.)

TREES and shrubs with brightly coloured bark can be made to produce very striking effects in autumn and winter, and they are most welcome at a time when scarcely any flowers or even fruits are left to brighten our gardens. Perhaps the most popular of those belonging to this class are the Willows with yellow, red, or blue-white stems (*Salix vitellina*, *S. daphnoides*, &c.). The Brambles mentioned in the following notes constitute a useful group, although their stems do not present the variety of colour seen in the Willows, all of them being of a blue-white, although of different shades. There are about half a dozen species of *Rubus* possessing this character, but the one here illustrated is, I consider, by far the finest, both as regards its size and vigour and the peculiarly vivid colour of its stems. Of this, the illustration, I think, affords abundant evidence. The whitish substance which covers the bark is a waxy secretion, very common on the different parts of many plants, although rarely so abundant as in this *Rubus*. One sees more or less of it on the stems of most hardy Bamboos, and it is very frequent on the stems and leaves of succulent plants. It can, of course, be easily rubbed off.

There is one quality these white-stemmed shrubs possess which does not pertain in any special sense to shrubs as a whole. This is their peculiarly striking effect in the moonlight. I have frequently had occasion to pass the group of Brambles here figured on bright moonlight nights in winter, and have always been impressed by the strange, almost weird, effect produced by the thicket of white wands contrasted with the dark masses of evergreens behind.

The cultivation of this Bramble is very simple, it is chiefly a matter of good soil and an annual pruning. It likes a good, sound, loamy soil, and what produces tall, thick stems also adds to their whiteness. Vigorous growths, too, retain their colour longer. Pruning should be done as soon as the flowering and fruiting season is over. All the stems shown in the engraving belong to the year 1898. Those of 1897 flowered last summer and afterwards bore

a little fruit; they were cut out some months ago. This is done not so much in regard to the health of the plants as to their appearance. After a winter's rain and fog (near London at all events) the white bloom on the stems wears off or becomes dirty, and in any case the stems are only biennial.

RUBUS BIFLORUS.—Although brought to this country from the Himalaya in 1818, its great value for the particular purpose under discussion does not seem to have ever been fully recognised. It is either not mentioned in catalogues at all or is confounded with *R. leucodermis*, which is not only quite distinct (and not so good), but comes from North America. At Kew, *R. biflorus* has stout, arching, spiny stems, 10 feet high and 1 inch in diameter at the base, the upper part

R. OCCIDENTALIS.—According to Aiton this shrub was introduced in 1696. It grows some 5 feet to 6 feet high, its arching stems being of a duller blue-white than those of *R. biflorus* and much less formidably armed, the prickles being small and far apart. The flowers are white and the fruit purplish black. It is a native of the Eastern United States and Canada, where it is known as the Thimbleberry or Black Raspberry. From it have been derived what are known in America as the "Gregg" and "Hillborn" Raspberries.

R. LEUCODERMIS is the best known of these white-stemmed species in nurseries and gardens. It does not appear to be so strong a grower as *R. biflorus*, and the bloom on the stems is not so vivid a white, but more distinctly blue. The

The white-stemmed Bramble (*Rubus biflorus*) in the Royal Gardens, Kew. From a photograph by G. Champion.

forming a spreading head of white prickly branches. Each leaf has five leaflets, which are also whitish beneath. The flowers are white, too small and few in number to be of any account, and the fruits are yellow. The plants in the picture were raised from seed four years ago.

R. LASIOSTYLUS was first discovered and introduced by Dr. Augustus Henry, whose name has in late years become so prominent in connection with new Chinese plants. He found it in the Hupeh province in China and sent seeds to Kew, the plants from which flowered in 1894. The flowers are small and reddish purple, and are too fleeting to add much to the beauty of the plant. The stems are about 4 feet high, erect, densely set with prickles and covered with a blue-white bloom. It does not promise to equal *biflorus* or even *occidentalis*.

flowers are white and the fruit yellowish red and of good flavour. It is a native of North-west America and was found long ago both by Douglas and Menzies on the shores of the Columbia River.

R. NEGLECTUS was sent a few years ago to Kew by the Arnold Arboretum. It is the strongest grower of these American white-stemmed Raspberries, being about 8 feet high. The stems are not so well coloured this year, but in some seasons they have been very striking, the bloom on them being white with a decided tinge of blue. It is thought to be a hybrid between *R. occidentalis* and *R. strigosus*. The fruit is dark red.

R. STRIGOSUS is another of these glaucous-stemmed Raspberries. It is a native of North-eastern America, and reaches from Labrador southward to the mountains of South Carolina. It is allied to *R. occidentalis*, but differs in the

stems being covered with bristles rather than prickles. The fruit also is red. A common name for it is Wild Red Raspberry, and it is the original of the "Cuthbert" and "Hansall" races of cultivated Raspberries.

These species are of only secondary importance compared with *R. biflorus*, which is the plant to grow for the colour of its stems; *R. leucodermis* and *R. occidentalis* are the next best.

Kew. W. J. BEAN.

The blue-flowered Hydrangea.—Everybody knows and admires the blue Hydrangea, but what is still not well known is how to produce the blue flowers. In the way of mixtures, what has not been tried in order to impart this blue to the flowers of Hydrangeas—soils obtained from slate quarries, powdered slate, ferruginous soils, sulphate of iron, &c.—in a word, a heap of materials and ingredients not always at hand nor easy to procure. The compost which I recommend is, on the contrary, within the reach of everyone, and it simply consists in the use of coal cinders. The mixture which I have used for five years to impart the blue colour to the flowers of my Hydrangeas is one-third peat soil, one-third leaf compost, one-third coal cinders.—ERNEST BARR, in *Le Jardin*.

PUBLIC GARDENS.

HAMPSTEAD HEATH.

IN accordance with the wish of the Hampstead Heath Protection Society that I should report on the present state of the Heath, and what may best be done for its future preservation, I beg to submit the following.

As to the wish to preserve the Heath in its natural state as far as possible, this is so right a desire from all points of view, and being, moreover, settled by Act of Parliament, it is needless for me to write anything in support of it, but as a planter I may say that there is no reason whatever why this wish should not be successfully carried out. The existence of stupid planting and jerry building is no proof that there are not better ways, and it is just as practicable and, with a little thought, as easy to group and mass in picturesque ways the vegetation most suitable for Hampstead Heath as to plant trees like lamp-posts, and attempt to adorn it with mere samples of the conventional "shrubby." The artistic and picturesque ways in which shrubs and trees may be planted, with some thought as to their nature and habits and mature effects, is by far the best for the health, beauty and endurance of the trees. Willows in a marshy bottom or Furze on the sandy knolls will live longer and look far better than the common middle shrubbery, of which there is an example on the Heath at the edge of the Viaduct Pond. Here trees and shrubs from many parts of the world are thrown together as in a shrubbery in a St. John's Wood villa, without regard to anything but their size as they left the nursery, and so jumbled together that they can but kill each other and never produce any good effect.

WHAT TO PLANT.—As to this vital question, I feel strongly that this is a place for our native shrubs and trees, which are very much neglected in ordinary planting; and not the more popular native trees only, like the Birch, Beech, and May, but such trees as the

true Aspen and field Maple, and among shrubs the native *Viburnum* of the woods in the home counties, which are rarely planted and never massed in picturesque ways as they should be. The result would help to teach the lesson that our native trees and shrubs are as beautiful as those of any other country, and it would also be a charming contrast to the parks, in which conventional trees of the nursery are usually the only ones planted. Whatever is planted should be grouped or massed in picturesque ways in the best sense natural, and thus what in conventional "laying out" might be called defects of the ground could be made to add to its beauty, the most rugged and broken surfaces lending themselves to native trees and shrubs perfectly. Even the wretched cinder heaps which disfigure one part of the Heath might be made pretty with Sloe, Furze and Broom, avoiding the labour of levelling the ground, but simply planting or sowing it with native shrubs, and fencing out sheep, rabbits, and other creatures for a few years. Mowing the surface of the grassy parts of the Heath is harmful, as tending to prevent the blooming and seeding of native plants like the Hairbell, and the practice should be forbidden, as should all clipping of trees "to get them into shape," which only means robbing them of that grace of form and variety of outline which Nature has given them.

POOLS.—There has been a filling up or disappearance of small pools on the Heath, owing partly perhaps to the drought of the last few years; but all the larger natural pools should be kept, not only for their value in reflecting the light, but also to encourage that graceful native vegetation which only grows by the margins of water. Where possible the natural drainage of the Heath should be kept above ground, and the small watercourses and ditches preserved.

PONDS.—In the fine series of ponds at Hampstead a mistake has been made in destroying the water plants, and disfiguring the margins by forming them into hard, ugly lines—the result of thoughtless cleaning of the ponds, when not only the native plants were taken up, but the ground lines characteristic of the margin of water destroyed. The result is as ugly and unnatural as anything could be, and a loss not only of the effect of the vegetation natural to the waterside, but also as regards food and cover for water birds.

When I last walked round these ponds at the end of May there were several miles of bare, ugly margin (in some cases 3 feet high) hard over the water. All the bolder native water plants should be restored, and many fine plants that naturally grow on the banks near water might be easily grouped here and there, and their growth would help to conceal the false lines of the present margins. In some cases ugly boards are used to form the margins, which might be easily hidden by a belt of water and waterside plants. In any

future cleaning of the ponds, both the waterside plants and margins should be taken care of. Even in ponds used for bathing it would be easy to keep a rich belt of vegetation and leave ample space for access to the water, but in large ponds where there is no bathing such a state of things is deplorable in a place which is supposed to be kept in a natural state.

THE AIRY EFFECTS AND NATURAL LINES OF THE GROUND TO BE KEPT.—Whatever is done in planting, the open, breezy character of the Heath should be preserved. It is only thus we can get the pictures and effects which distinguish Hampstead from other open spaces in and near London. Such pictures it is well to keep, and not for artists only, as many who never possess painted pictures feel the beauty of the real ones they see here. Much ordinary planting would be destructive of the open and airy character of the Heath; and where common vigorous trees have been planted, as on the east side of "The Spaniards" road, so that in time they will obscure good views or the foregrounds of such views, they should be removed and massed where they can do no harm to the character and beauty of the Heath.

Attempts have been made to shoot earth and rubbish to fill up the hollows on the Heath; and as the surrounding district is busy in building, these attempts are likely to be repeated. Therefore the bringing on the Heath of such rubbish should be absolutely forbidden, as the only effect of this filling up of hollow places will be to destroy the natural incidents of the ground, usually far prettier in form than the results of smug levelling up, or, worse still, the formation of such artificial mounds as we see examples of in the parks.

BARE AND WORN BLUFFS.—There is a considerable area of bare bluff in the Heath which, in the absence of crowds, would be soon covered with vegetation; and as these bare places are hot and unpleasant to look at and occupy much surface which might be more beautiful, it will be well to sow Furze, Broom, Sloe, and a few of our native shrubs there, protecting them from injury for a year or two until they can take care of themselves. This plan need not imply the barring of access up and down such bare bluffs, as it should be easy to keep open the more frequented paths.

DEFACEMENT OF THE HEATH BY NEEDLESS STRUCTURES.—The erection of these, no matter on what pretext, should be carefully watched, as in such a place they are certain to lead to needless cutting up and spoliation of the surface, and to the ruin of the landscape effects. The chief charm of such a noble piece of broken and picturesque ground is in giving a place of escape from the noise, fuss, and often too facile conveniences of the town; and I think there is likely to be a more insidious danger to the Heath in the future from mean and frivolous structures than any other single cause.

FENCES.—Where a fence of any kind is required in the foreground of a Hampstead picture, rent Oak should be used instead of

the usual cast-iron, which is destroying so much the beauty of the landscape in the home counties. It is best to avoid fencing wherever it is possible to do so, and any iron at present in use on the Heath should be kept for its best use, viz., supporting wire for the temporary protection of plantings from browsing animals of all kinds, without which no successful planting can be carried out.

HEATH PATHS.—The introduction of the conventional park or garden path would be deplorable here, and the aim should be to keep to the best of the beaten paths. The public help very often in the formation of good paths by taking the line of easiest grade, which is often a good line. But where, as in a few parts of this Heath, too many paths occur, owing to the very great crowds, it is not well to give way to the surface being wholly destroyed, and it would be well to keep the best of the paths and widen them with care, keeping their free margins—and, where much surface is saved in this way, sowing native shrubs—with temporary protection until they were strong. As to the surfacing of the paths or drives, no ill-coloured rubbish, like cinders, should be used, as they have been here. Where the colour of the gravel found on the Heath is so good, we should be careful not to use black or ugly colours on roads or paths.

CARE OF THE HEATH.—Such a vast and precious space, liable to danger from without as well as in other ways, should not be left wholly to take care of itself. In a state of nature, or freed from crowds, it would soon become a thicket or a wood; but, with the vast crowds that pour over it, constant care and thought will be required to renew the planting and save the old trees and all else worth preserving. A ranger who knows our native trees and shrubs well should be in charge of the Heath, whose duty and pleasure it would be to keep the Heath as a heath, and not merely follow the conventional ways of parks, and who could be appealed to readily by those interested in the preservation of the Heath. W. R.

Bamboo stakes.—Bamboo stakes, lately inquired about, are much more lasting than wood and neater, too, but one drawback possessed by them is that they do not grip the soil as wooden stakes do, and therefore, if the plant sways about in the wind, they are very apt to get loose. This is owing to the highly-glazed surface of the cane. One other item to bear in mind is that they are hollow, and the upper portion sometimes affords a home to earwigs and other insects, but this can be readily prevented by stopping up the hole at the top.—H. P.

Wire trellis for walls.—In your issue of THE GARDEN for the 12th ult. (p. 393) there is a note by Mr. Hudson re "Injury to wall trees from wire," with a supplementary note by the editor on latticing walls with Bamboos and Chestnut or Oak. I shall deem it a great favour if you will let me know your method of fixing Bamboos to the wall, and if best done in diamonds. It is intended to build a stone wall round the kitchen garden here (stone being plentiful through some alterations), and as I believe wire to be very harmful to wall trees, I shall be glad to know of some suitable substitute.—WILLIAM PLANT.

Your question is so very interesting, that we hope that some of our correspondents who feel

as we do about the matter will help you. The ordinary old French and English way was to tie the trellis-work of Oak or Chestnut into lengths of, say, two yards or so, making it in the winter under cover, and then attaching it in spring to the walls by holdfasts. In making a stone wall now ourselves we put in strong eyes here and there to attach such trellis-work to—say about every yard of the wall or so—and these when our trellis is ready will be very handy. For Peaches we should say squares of 10 inches would be the best. For Pears and stronger trees we are putting into the wall strong galvanised eyes about 1 foot apart, so that it will be easy to tie the branches to them, and if for any purpose we want to tie or train the young wood, we can easily run a Bamboo or other stick from eye to eye.—ED.

ORCHARD AND FRUIT GARDEN.

APPLE MALTSTER.

My attention has been called to some remarks by "A. D." (page 395) anent the hardness of the wood of this very excellent dessert Apple. When "A. D." says "the wood is so tender that entire trees have been killed during very severe winters," it is very evident there must be a spurious variety about, and those who make that assertion or supplied such information must have been victimised. My experience is the very opposite, and out of upwards of 250 named varieties there is no kind so hardy or that suffers less from frost than the Maltster, and there are at this and neighbouring places plenty of trees having boles upwards of a foot in diameter, whilst at Stoke Edith, I am informed, there is almost an entire orchard of very large trees of this variety in vigorous health, which have never suffered injury from frost.

I do not claim an equality in favour with such kinds as Cox's Orange, Ribston, Grafton, and similar kinds, but for a sweet, juicy, pleasant, soft-fleshed dessert Apple during the months of October and November it is far before many of the so-called early dessert kinds; moreover, the tree is a constant bearer, with a good constitution, a shapely grower, and ought to be included in the best dozen of dessert Apples grown on the Crab or free stock. The colour, being greenish, with a slightly flushed cheek where exposed, is somewhat against it as a market variety as compared with such highly coloured kinds as Worcester Pearmain and others, but which are certainly inferior in flavour to Maltster. At all events, when one finds the juniors perfectly unanimous in praise of the Maltster, one gets an unbiased opinion about the taste of the Apple, to say the least of it. The same verdict is expressed by more orthodox Apple eaters when presented at its best; but, unfortunately, like all the section of early kinds of Apples, the fruit does not long retain its crisp, fresh, agreeable, delicate flavour after being gathered and stored: nevertheless, I know of no Apple superior to it for the month of October when gathered from the trees at short intervals.

Perhaps if those who have had unfavourable experiences and whose trees have suffered injury by frost (if such is possible) would give some further details in the columns of THE GARDEN, some useful information may be arrived at, beneficial to fruit growers generally. Of course it would be necessary to give the kind of stock, the locality, and whether this kind suffered from frost more than other kinds growing alongside, with some description of the habit of growth and other particulars sufficient to identify whether spurious or otherwise. I should be pleased to present grafts of the true Maltster to applicants, in reason, at any time, so as to confirm the above statements.—W. CRUMP, *Madresfield Court.*

—Having read the note from "A. D." anent this Apple (p. 395), perhaps it will interest him to know that this variety is well known and grown rather extensively in this neighbourhood.

I also have Maltster, and, as far as I can learn and from my own personal experience of it, I find it to be anything but tender. On the contrary, it is as hardy as the generality of sorts, and it passed through the severe winter of some six years ago unscathed. I value it here as being an excellent flavoured Apple, and it remains in good condition until the end of October. In an orchard not far from where these lines are being written the fruits of this variety attain a large size, colour splendidly, and invariably return the owner a substantial profit when marketed.—A. W., *Stoke Edith, Hereford.*

Apple Margil.—The flavour of this variety is apt to vary in different soils and under different conditions, but as a rule it is distinctly good. It has seldom been better, I think, than this year, and fine fruit of it has been exhibited on several occasions. Being of a convenient size for dessert and a reliable cropper, it may with advantage be planted freely on good Apple soils. Where the soil is very heavy the tree is liable to canker, and the fruit in some instances has a very tough skin. It is, in short, an Apple that requires good cultivation to bring out its best points.—J. C. T.

Apple Red Streak.—Twenty years ago an Apple named Red Streak might be seen in orchards in South Essex carrying immense crops of fruits. Whether it was a local sort or not I do not know, but I have never met with it since nor have I ever seen it catalogued. I have wished I could get hold of it, as it is a never-failing bearer, while the fruits, which were about the size of King of the Pippins, very conical in shape and heavily streaked with red, were very juicy and well flavoured, coming into use in October and keeping fairly well. I have seen large boughs propped up to prevent the weight of fruit snapping them off. Probably it is grown under another name, but I have never seen it in any other part of the county so as to recognise it. Since writing these notes I have learned that this Apple is known by the name of Colonel Vaughan or Kentish Pippin.—J. CRAWFORD.

Large versus small pots for Strawberry runners.—Opinions are divided as to whether large or small pots are best for layering Strawberry plants, but much depends on circumstances. I can remember when large pots were always used, but then Strawberries were not forced in such quantities as they are in many places nowadays, though excellent fruit and early in the season was produced. One thing is certain, that by using large pots much time and labour are saved. The only objection I can see to the system is that in very wet seasons the extra bulk of soil in 6-inch pots is apt to get into an over-wet condition and the weaker-growing varieties start slowly into a free growth. On the other hand, there is often a difficulty in keeping plants in small pots moist at the roots in dry weather, especially if not plunged, and if, through press of work, a pot bound condition is reached, they are often slow in starting into growth when potted. In seasons like the one just past, runners from special stock plants are far better than those procurable from the very best fruit-bearing plants on exposed quarters, and their semi-shaded position favours early and free rooting. It would be next to impossible to layer into large pots on fruiting quarters unless much extra room were allowed between the plants, as the runners usually require layering before all the fruit is gathered.—J. CRAWFORD.

Fig Castle Kennedy.—It is now a good many years since this Fig was sent out at a high price, having been raised by the late Mr. Fowler, of Castle Kennedy. Thousands were distributed, but gardeners soon found that, although a fine variety, it was a very shy bearer, and for that reason it is not now very extensively planted. It is catalogued as a hardy variety, but it is not wise to plant it outdoors. Even when planted under glass these shy-bearing Figs ought, I think, to be assisted with a little warmth soon enough in the season to allow of the fruit ripening in August.

The wood then has a chance of becoming well ripened, an important point with capricious sorts. Of course, no one would think of planting Castle Kennedy except in a limited root-run. The soil also should be of a poor sandy nature and the compost largely consist of pounded bricks or mortar refuse. A plan which might be adopted with advantage is to form a basin by means of a turf rim. By top-dressing, fibrous roots are formed in abundance near the surface. These can be removed each winter with the knife and a fresh surfacing given. I have adopted this course with forced pot Figs, and the fruit did not drop the following spring. The plan of laying in an extra quantity of wood with a view to check grossness is an erroneous one. Better retain no more than can be exposed to sun and air, and modify growth by root restriction.—NORWICH.

SHY-BEARING APPLES.

It is all very well for those having plenty of orchard or garden space at command to plant slow or shy-bearing Apples for the sake of variety, but amateurs and others with only limited convenience ought to avoid these often disappointing varieties and plant those only that may be depended on for giving both a speedy and good return. Curiously enough, some of the very finest, most handsome varieties are the shyest fruiterers when in a young state. Take, for instance, Peasgood's Nonsuch. In some few soils and districts it may produce a few fruits at an early date, but the majority of trees remain doggedly barren for years, even though root-pruning and other cultural details receive strict attention. I had an espalier tree which for five or six years did not bear a single fruit, despite all the efforts on my part to induce it to do so. A friend of mine had a similar experience, although when his tree did commence to bear the fruits were magnificent. Warner's King is often classed as a profitable market Apple, which it undoubtedly is when growing in soil that just suits it, but my experience of it, both in standard and the more restricted espalier form, is that it is very uncertain both as to when and how it will yield. I have known it planted in a cottager's garden and fruit looked for in vain for years. I am told it is more prolific on the Paradise stock, but have not proved it. Some think Warner's and Cobbett's Fall one and the same Apple, but I do not, having grown them both in various forms. I found Cobbett's Fall not only much freer in bearing but also of a richer colour; in fact, on a standard in a sunny position the fruit took on a beautiful bronzy hue on the exposed side. Some might be induced from seeing fine fruit exhibited to plant King of Tomkins County in standard form, but unless the soil and situation are warm, failure may be apprehended. The same may be said of Alexander, an Apple unsurpassed either for size or beauty when grown on cordon trees in warm places. Blenheim Orange is well known to be a slow Apple, but it has this redeeming feature—that when once it arrives at a bearing state it remains fruitful. Bramley's Seedling is a much over-rated Apple. In strong loam it fruits fairly early, but in ordinary soils it sometimes remains unfruitful for ten or fifteen years. NORWICH.

PEARS.

ALTHOUGH one often has to complain of a superabundance of ripe Pears at some particular time, and then a difficulty in finding them, I think the glut is even more pronounced than usual so far as the early part of November is concerned—a state of things probably due in a great measure to the prolonged spell of dry weather and a premature finishing of the fruit. I left them, too, on the trees later than usual this season in the hope that the ripening might be somewhat delayed. At the present time I have ready Marie Louise, Beurré Hardy, Doyenné du Comice, Van Mons Leen Leclerc, Durondeau, Thompson's, and Beurré Alexander Lucas, and I have picked

out ripe fruits of Nouvelle Fulvie and Glou Moreau. I planted Thompson's and Alexander Lucas some few years ago on the recommendation of a well known grower, and am very pleased with them. The former kind is rather small with me, but a good cropper and excellent in flavour, whilst the other comes of extra size, also crops well, and, if allowed to ripen out thoroughly, is a really fine Pear. The duration of the ripening process, or rather the exact time when different varieties are at their best, is a subject requiring careful study alike as to sorts and to the character of soil in which they are growing. Here, for instance, sorts like Van Mons, Beurré Hardy, and B. Superfin must be sent to table as soon as they will yield to a rather firm pressure, whilst Marie Louise, Alexander Lucas, Doyenné du Comice, and Glou Moreau can be kept until the fruit will only bear the slightest pressure. If asked to name one of the best and most useful Pears, I should unhesitatingly give Glou Moreau. It is a great and consistent cropper, comes in when the bulk of varieties is over, and has certainly about the longest season of any, especially where trees can be planted in different aspects. This with Winter Nelis and Josephine de Malines is the best late Pear here. Neither Bergamote d'Espere, Beurré Rance, nor Eister Beurré ever ripened sufficiently to be worth eating, and I have removed them in favour of other sorts. I have gradually removed very old trained trees and replaced them with cordons, but one of the few remaining is a variety of Bergamot that ripens towards the latter end of November and is an excellent Pear. It is between the old Autumn Bergamot and Gansel's in size, richly flavoured, the flesh firm, sweet, and juicy. It may be only the old variety with size and quality altered by the protection of a wall, and the season lengthened from the fact that it is on a north-west aspect.

Claremont, Surrey.

E. BURRELL.

THE BEST PEACHES IN FRANCE.

WISHING to compare the best Peaches cultivated in England with those cultivated by the best growers for the market in France, we are indebted to Mons. Vitry, a distinguished cultivator of Montreuil, for the following list of the best kinds grown in that famous town for Peaches, some of which, it will be seen, are little known in England:—

First early kinds.—Amsden, Alexander, Hale's Early.

Early kinds.—Grosse Mignonne Hative, Grosse Mignonne Ordinaire, Madeleine de Courson.

Midseason.—Galande, Bellegarde, Belle de Vitry, Henri Pinard, Alexis Lapere.

Late.—Belle Beauce, Belle Imperiale, Bonouvier.

NOTES AND QUESTIONS.—FRUIT.

Plum Prince Englebert.—I know of no other blue cooking Plum which grows so large as Prince Englebert. I do not think it is one of the most certain varieties; at least, I confess I have never been very successful with it. One sometimes sees vigorous, well-cropped trees, and I remember seeing such an one in the south of England. It occupied an east wall space of about 15 feet by 12 feet. One good point is that it will hang a long time on the tree in good condition.—NORWICH.

Peach Dagmar.—I do not claim for this Peach the richest flavour, but it is a very useful variety, and a good one to grow where only rough and ready treatment can be given. I grew it in a second early house where the fruit ripened in July. The tree is a great bearer, and the fruit, which is about the size of Stirling Castle, takes on a fiery red colour. It is juicy and refreshing and would make a good amateur's Peach. I can only speak of it as grown under glass, as I have never tried it on an open wall.—C. N.

The weather in West Herts.—A very cold and wet week. On two days the shade temperature at no time rose to 40°, and on the coldest night the exposed thermometer registered 10° of frost. At the present time the soil is at about a

seasonable temperature at 2 feet deep, but about 3° colder than is seasonable at 1 foot deep. During the last ten days 2½ inches of rain have fallen, making this the wettest consecutive ten days since September, 1896, or for more than two years. At 9 p.m. on the 28th ult. my garden was covered with snow to the average depth of 1 inch, but this fall was soon melted by the comparatively warm ground. During the past thirteen years there have been only three Novembers as warm as the month now ending, for I am writing this report on the last day of it. Throughout the first three weeks there did not occur a single unseasonably cold day, and only three cold nights, but the temperature was often quite wintery during the last nine days of the month. Rain fell on fourteen days to the aggregate depth of nearly 2½ inches, which is slightly below the November average. Nearly the whole of this total has fallen during the last ten days, previous to which there had been no rain worth mentioning for more than a fortnight. The record of bright sunshine was somewhat in excess of the mean for the month.—E. M., *Berkhamsted*.

SOCIETIES AND EXHIBITIONS.

NATIONAL CHRYSANTHEMUM SOCIETY.

THE executive committee of the above society held a meeting at Carr's Restaurant, Strand, on Monday evening last. The chair was taken by Mr. T. W. Sanders, and he was supported by a fairly full muster of members. The usual preliminaries of minutes and correspondence having been disposed of, it was announced that the late treasurer had written thanking the society for the testimonial presented to him on his retirement from office. A letter was read by the foreign secretary from Mr. Briscoe Ironside, giving some interesting details concerning the progress of Chrysanthemum culture in Italy. There was also a communication from the secretary of the French National Chrysanthemum Society, thanking the committee for the cordial reception accorded to their representative to the recent Aquarium show, and expressing a hope that a deputation of the English society might visit the conference at Lyons next year. A report was read from the sites sub-committee setting forth the proposed arrangements with the Aquarium Company for holding next year's series of exhibitions there, and the same was agreed to. The secretary, Mr. Dean, announced that the prize money awarded at the November show amounted to £330 19s. 6d., and that one gold, seven silver-gilt, ten silver and ten bronze medals had been awarded. A rough statement of assets and liabilities was then submitted and considered satisfactory. It was resolved that the floral committee should fix the dates of its meetings for 1899, and that that committee be invited to dine together at the conclusion of the meetings as in former years.

Several offers of special prizes were considered, and the meeting closed with the election of sixteen new members.

Gardeners' Royal Benevolent Institution.—We are asked to state that the Reigate and District Chrysanthemum Society have forwarded through Mr. J. Brown a donation of £21 to the funds of this institution.

The Royal Gardeners' Orphan Fund. The next election of children to the benefits of this fund, consisting of an allowance of 5s. per week until they attain the age of fourteen years, will take place early in February. All applications must be made on a proper printed form, copies of which may be obtained gratis of the secretary, or any of the local secretaries. Such forms must be correctly filled up, duly signed and returned to this office by Tuesday, December 20, 1898. A. F. BARRON, *Secretary, Chiswick*.

— At a meeting of the executive committee held at the Horticultural Club on November 25, Mr. A. W. G. Weeks in the chair, the following special donations were announced: Mr. W. Bryant,

sale of flowers at the Rugby Chrysanthemum show, £7 5s.; Mr. J. Hughes, Birmingham, box, £4 3s. 4d.; The Sevenoaks Gardeners' Society, per Mr. Cooke, £4; Mr. R. Scott, Bradford, box, £1 10s.; Messrs. G. Bunyard and Co., Maidstone, box, £1 5s. 2d.; Mr. W. Bates, Twickenham, box, £1 4s. 6d.; and the Chiswick Gardeners' Society, box, 10s. It was announced that Mr. William Nutting had consented to take the chair at the social supper to take place at Anderton's Hotel on the evening of the annual general meeting, on February 17.

Italian National Chrysanthemum Society.

—The first annual exhibition of the Italian National Chrysanthemum Society was held at Milan from November 10 to 15. It took place in the Fine Art Gallery, and a finer, lighter and more suitable building for such a show would be difficult to find. The majority of the exhibits were pot plants. Mr. Briscoe-Ironside had a room to himself, which he completely filled with examples of every section of the Chrysanthemum, and also with plants. For this he was awarded a gold medal. The floral committee held a meeting, but awarded only two first-class certificates. These went to M. Ernest Calvat for the following: Princesse Bassaraba de Brancovan, a large Japanese of the C. B. Hayward type, and Lesdiguières, also a Japanese of large size, pale orange, streaked crimson. At the show there were eighty-four competitors in the forty classes. On this occasion the executive of the Italian society issued a very attractive and interesting special number of its journal, "Il Crisantemo." This publication consisted of thirty two pages, and was enclosed in a coloured wrapper with a tasteful allegorical design.—C. H. P.

NOTES OF THE WEEK.

Physianthus albus in fruit.—I am sending you some fruit of *Physianthus albus* grown outdoors in these gardens. The plant is on a south-west wall. I never saw the fruit so large before. There are about two dozen fruits altogether.—EDWIN CLEMENTS, *The Gardens, Caerleon, Killiney, Dublin.*

Paper-white Narcissus.—Twenty years ago it was considered early if this plant was brought into bloom at Christmas or the end of the year, while at the present time it is easy to get the plants to flower at the end of October. For some time past bunches of it have been noted in the streets, and at Kew some two or three weeks since many examples were in full flower in the greenhouse in pots.

Poinsettias.—It was easy to see by the excellent examples of these brought from Tunbridge Wells to the Drill Hall last week that no London fog had been hitherto in contact with them. The colour of the bracts was generally remarked; indeed, they were the only things present at the meeting in question possessing any approach to brilliancy of colour. The plants were admirably grown, carrying the fine foliage quite low on the plants, and in vigour, as much as in size and colour, denoted good culture.

Epiphyllum truncatum Princess.—Perhaps many were surprised to see this plant obtain a first-class certificate at the hands of the floral committee last week, when already there are so many beautiful things in commerce. As a class, however, these beautiful subjects are not well, or even generally known, hence the reason probably of the award. It should, however, be stated that the majority of kinds, if much larger in size, possess deeper coloured blossoms, varieties with the delicate pleasing tone of Princess being considerably in the minority.

Pernettya mucronata.—Whether as pot plants for the conservatory or for massing in beds in the flower garden, *Pernettya* are alike useful and attractive also by the profusion of berries the plants produce. In the rock garden, too, such things would prove of considerable service when almost all the occupants are at rest. The plants may be so grown during the summer as to form a subordinate crop, so to speak, or they may occupy permanent positions in the rock garden, and thus play their part in prolonging the display.

Crassula lactea.—Among easily-grown plants useful for winter flowering the above is not

worthy, the plants both blooming freely and lasting a long time where the air is fairly dry and but little atmospheric moisture prevails. The plants are impatient of much root moisture at the flowering period. The species is as valuable for baskets as it is for pots, and in the former, advantage may be taken of its longevity without much added moisture, the succulent character of the plants affording almost all that is needed.

Erica hyemalis.—The past hot, dry season appears to have been very favourable for this useful winter-flowering Heath. I have never seen it better flowered or more plentiful than this season; in fact, the London markets have been rather overstocked, and many plants have had to be sold at prices that could hardly prove remunerative to the growers. There are now three distinct varieties—the normal form, a pure white variety, and one called *superba*, which has larger flowers and the lower portion of the tube of a deeper pink. It is a strong grower, but does not flower so freely as the type.—A.

Erigeron mucronatus.—This little Mexican Daisy, so often referred to in *THE GARDEN*, is yet in flower (November 26) in the rock garden here. An almost continuous bloomer throughout the summer, it is even more valued now that rock garden flowers are scarce. This *Erigeron* is a true perennial, but is a little too tender to stand our most severe winters except on a very dry soil. Here one need care little for the effects of the hardest frost so far as old plants are concerned, as seedlings appear in profusion and have to be thinned out, or they would become troublesome.—S. ARNOTT, *Carsethorn, by Dumfries, N. B.*

No hardy flowers in summer.—I always thought our friends who believe there are no hardy flowers in July and August had rather a dim vision, and I am surprised to find my friend Mr. Meyer in the same boat.

July and August, as a rule, are dull months with regard to most hardy flowers. The early things are over and the late flowers have not yet commenced to bloom. Doubly welcome, therefore, are flowers that bridge over the gap and look bright and cheerful during the months mentioned.

No hardy flowers in July and August! This on the face of all the lovely Tea Roses for those who grow them well and all the fine border Carnations, not to speak of Water Lilies, a whole garden of Lilies, and brilliant and tall Lobelias. People who think July and August dull months do not do their duty about hardy flowers.—BROOKSIDE.

Verbena venosa.—As a hardy herbaceous perennial this plant is worthy of notice, and may with advantage be much more largely grown, as the colour is by no means unattractive in a mass. In some gardens the plant is employed as a permanent edging, and in this way plays a somewhat important part in the display. It frequently happens, however, that with increasing years such edgings become more or less exhausted, and means should be taken to secure a fresh crop of young plants either by division or by seeds. In exceptionally severe times frost will render the plants patchy, but this is not frequent, and may be prevented by a covering of ashes, leaves, or cocoa fibre placed on the plants now, or a portion of the stock may be boxed and placed in frames. The former is the better way, however, as the old plants at this season often die as a result of the disturbance.

Scilla italica alba.—Looking through a volume of Maund's "Botanic Garden" to-day, I came upon the plate of *Scilla italica* and its white variety. The former is far too little grown, and some time I may have a little more to say regarding it. It is, however, of *S. italica* alba that I desire to speak, hoping that it may be brought under the notice both of trade and private growers. I was on the look-out for it for some years, but could never ascertain where it was to be had. About three or four years ago it was offered in a Dutch catalogue, and I secured a bulb. This did not flower, and died the following winter. This white Italian Squill is not now

offered in any of the catalogues with which I am acquainted. Probably there are other admirers of hardy bulbous plants who may not know that there is a white variety of *S. italica*, and a demand for the same may call forth a supply.—S. ARNOTT.

Abutilons for winter flowering.—"H." (p. 432) refers to the value of these beautiful plants, and mentions having had no opportunity of trying them away from London. "H." however, is quite right in his estimate of their value in the purer country air. Some years ago I grew a large collection, but I found none so really profuse and free in midwinter as the old *Boule de Neige*. Subsequently, among others, *Golden Fleece* was given a trial, and, if anything, I believe it is a more profuse and abundant bloomer than *Boule de Neige*. No others equalled this pair in these respects, while in point of colour *Golden Fleece* is a variety deserving great praise. It is this variety that is so marked a feature in one of the greenhouses at Kew. A fine plant, with its roots in soil beneath the stage, spreads its twigs over a considerable roof space and flowers freely for months. It is surprising, too, seeing the nearness to the river and the havoc which the fog plays on many good things in these gardens, that this *Abutilon* is so hardy and enduring. Only recently the large plant referred to was literally covered with its richly-coloured flowers.—J. C.

OBITUARY.

ROBERT B. PARSONS, OF FLUSHING.

We regret to learn that Mr. Robert B. Parsons was run over and killed by a train on the Long Island Railroad at Newtown Station on Tuesday, November 1. Deceased was one of the best known and most respected men in Flushing, where he has spent his lifetime, and where he was born in February, 1821. His father, Samuel Parsons, established a nursery business for his two sons, Robert and Samuel. The land connected with the nursery extended over two hundred acres, and the business done by the Parsons was a very extensive one, extending to every section of the Union, to Mexico, and to Europe. Both Robert and Samuel B. Parsons made frequent trips to Europe, and also became interested in the trees of Japan, and were among the first to introduce them to America. The firm was dissolved in 1872. Samuel Parsons, with his sons, established the Kissena Nurseries, while Robert Parsons continued the business at the old place.

Mr. Whittall, of Smyrna.—Our readers will regret to hear that this gentleman, who has done so much to enrich our gardens with rare bulbs and seeds from Asia Minor, has recently been captured by brigands. The following note appears in London papers:—

Mr. Whittall, a British subject resident at Smyrna, who was recently captured by brigands in the neighbourhood of the town, was released on Saturday evening. The Sultan, on hearing of his capture, immediately sent orders to the Vali of Smyrna to do all in his power to procure Mr. Whittall's release, and even, if necessary, to pay the ransom demanded by the brigands.

Mr. Whittall is to be congratulated on his lucky escape, and we sincerely hope that his adventure will not deter him from continuing to explore the mountain flora, from which he has sent us so many fine and new Snowdrops, Scillas, Chionodoxas, Tulips, Irises, &c., during the past ten or twelve years. A portrait of Mr. Whittall was given in *THE GARDEN*.—F. W. BURBIDGE.

Names of plants.—H. H.—1, *Cyrtanthus McKeni*; 2, *Angiopteris erecta*.

Names of fruit.—J. McKenzie.—Peer Pitmaston Duchess; Grapes so small it is impossible to verify.—R. C. Coope.—Apple Rymer.—W. Ingram.—1, Col. Vaughan; 2, Pennington Seedling; 4, King of the Pippins; 5, Cox's Pomona; 3 and 6, next week.

THE GARDEN.

ORCHARD AND FRUIT GARDEN.

UNSUITABLE SITE FOR AN ORCHARD.

A SHORT time ago I remarked in THE GARDEN that the question of disposing of a piece of land often leads to the formation of orchards when the soil and situation were more or less at variance with the essential conditions to successful hardy fruit culture. Recently, in South Wales, a striking example of this kind came under my notice. A narrow belt of land in a hollow by a riverside, backed up by hills on the west and south, and exposed to the full force of the winds from the north and east, was being planted with Apple, Pear, and Plum trees. A more undesirable position for an orchard could scarcely be found. Here the fogs and vapour from the river will retard the maturation of the wood in autumn, and aid the frost in spring in destroying the fruit-buds and blossom. The dry, cold winds from the north and east, having full play, will abstract the moisture from the flowers, paralyzing and destroying them. With these evils to contend with, the chances of successful results are very remote. With good soil to root in and liberal treatment in the way of manure, the plants may grow apace, quickly attaining good-sized trees, which the absence of fruit will foster. For ornamental purposes the situation and aspect are wrong, for the plants, if at all maintained in a healthy condition, will be sparsely flowered, and the few fruits the hardier sorts may bear will be small compared with the normal size of the variety. Besides, should cold, cutting north or east winds prevail at the time their weak, scattered flowers are unfolding, they will be practically shrivelled up in the bud, so that a display of blossom as well as fruit may only be looked for in exceptionally propitious seasons. The moist atmosphere, too, will not only mar the prospect by frustrating the maturation of the wood and facilitating the destructive agency of frost, but it will also foster the growth of Moss on the trees—an evil every intelligent fruit grower

guards against. A few old specimen Apple and Pear trees not far from the new orchard referred to bear testimony to this pernicious tendency of the saturated surroundings, for they are literally feathered with Moss from the ground to almost the end of every shoot.

With such a practical lesson as this of the unsuitableness of the site for an orchard, no fruit grower familiar with the conditions under which successful cultivation can be secured would ever entertain the idea of utilising such land for the production of hardy fruits. It is in cases like the one mentioned that energy, enterprise, and money are wasted, because the situation is a very bad one, the aspect the worst that could be chosen, and the atmospheric conditions everything but those which should obtain. There are many unprofitable old orchards in the country due to one or more causes, but one would scarcely expect to see new ones started under such unfavourable circumstances as I have just described, considering the amount of instruction in such matters conveyed through the horticultural press for the benefit of those whom it should interest. The best site for an orchard is one falling to the south, the land well drained, sheltered from the north and east, and some distance above and from water. In such a position, provided the soil is suitable, the plants well fed, and the seasons at all favourable, good results may rationally be expected.

J. RIDDELL.

Pear Beurre Diel.—In the majority of gardens I have always found the above a favourite, and "Suffolk" (p. 416) does well to call attention to its good qualities, as it appears at home in most soils if well drained. I am not quite sure if I can go so far as "Suffolk" in advising it for heavy soils, as in such I have seen poor fruits and badly cracked. Drainage is one of if not the chief cause of failure, and the good crops this year in heavy, poor soil would be greatly influenced by the drought this year and last. My best fruits are from trees on a sloping bank, the soil being very light. I have other trees on walls in heavy soil, but on these the fruit is much smaller, nearly

covered with russet, and lacking the clear yellow skin of those in better drained soil. In wet seasons the fruits in the heavy soil crack. This variety does well as a cordon on a warm wall.—G. W.

Pear Thompson's.—Many omit to include this excellent variety in their collections. Those who study quality will do well to give Thompson's a place, as I do not know of any October Pear with superior flavour. Of course, Doyenné du Comice will be selected in preference to Thompson's, but with me Comice is a little later and can be better termed a November fruit, Thompson's being at its best in the third week in October when grown in a warm, well-drained soil. In my opinion it is little inferior to Comice as regards flavour. The trees do not always thrive on the Quince. I have trees on the Pear which rarely fail to crop, but the best trees are those double-worked. Given this, it makes a grand wall tree, and is also more suitable as an espalier. It does not thrive in cold soils or exposed positions.—G. W. S.

Apple Cornish Gilliflower.—It is curious that this variety should be so highly prized when its shy-bearing and ugly-shaped fruits are considered. Its quality as a dessert fruit is not superior to that of Cox's Orange or Ribston. If it were, some reason would be furnished for the high position given it by some growers. Cox's Orange being equally fine flavoured, a better grower, and a much more handsome fruit, what need is there for planting such an uncertain sort when there is but one favourable point in its character? I have never yet planted a Cornish Gilliflower, and it would take a deal to convince me of its claim for favourable notice. Mr. Burrell says he finds that, unless his trees are carefully netted, birds soon spoil the crop. The same thing occurs here with Gravenstein, another Apple possessing a very pronounced aroma, so strong, in fact, that it can be detected several yards distant from the tree. Wasps are attracted for the same reason. Where wasps, hornets, and small birds are so persistent and numerous—and this occurs in some districts more than others—it is not a good investment to plant such sorts as these. I have compared Cox's Orange and Cornish Gilliflower from a flavour point of view and could detect no difference, and this is the

only point which has given fame to Cornish Gilliflower. I do not see any justification for the favour shown it.—W. S.

OVERCROPPING YOUNG PEAR TREES.

PEAR trees are often weakened and sometimes ruined by being overcropped in a young state. The soil and situation may be all that can be desired, but if the trees are not treated carefully when young, good results cannot be expected. Some varieties will take care of themselves, even needing root pruning to check growth and induce fruitfulness, but it is the early, free-bearing sorts that often get crippled at the start. I recollect seeing a lot of young Pear trees in a garden in Suffolk a few years ago. They had been planted the previous autumn, and being studded with fruit buds, and the soil being warm and well drained, they became established before winter—such free-bearing kinds as Louise Bonne, Beurré Clairgeau, and Doyenné du Comice fruiting freely the next summer. When I saw them in September some of the trees were laden with fruit, and I was not surprised to hear the following year that the trees were practically at a standstill, and would take some years to recover, if ever they did. Had this first year's crop been reduced to a third or even a quarter, all would probably have gone on well and the trees have filled their allotted space in a minimum of time. With older established trees the case is different; when overcropped they usually take a rest and have the power to recoup. Sometimes young trees bear fruit on the extreme ends of the leading growths. These should be removed, as they not only hinder the tree's progress, but spoil the leaders. Some gardeners summer-prune newly-planted trees whether the growth is strong or weak, whereas weakly trees should go unpruned the first summer. This, with mulching and watering and picking off any fruit that may appear, tends to lay the foundation of a vigorous and fruitful tree. J. C.

Pear Passe Crassane.—This variety is not so much grown as it deserves, as in a warm soil and favourable situation it is a splendid Pear. As a cordon I failed with this variety, but when the trees were given more freedom there was a better return. It does not do well on the Quince, and our leading fruit growers advise double grafting. I once had this variety on the back wall of a cool Peach case on a west aspect and obtained splendid fruits. We have so very few really good Pears after Christmas that any that can be grown are most valuable.—G. W.

Pear Glou Morceau.—This is a very fine variety when well ripened, and on a south wall in Wiltshire it used to bear freely, fine handsome fruit of delicious flavour being produced. Here I have it in the open and cannot say as much for it, though possibly it may be better when thoroughly established. The trees have fruited twice only. The soil is heavy, but the trees have been well fed and other varieties have done well. It would appear that this Pear, excellent as it is, needs a sheltered position such as is given by a wall as described. At its best Glou Morceau is a large and handsome fruit, good to the core and fit for the table by the middle of December.—SUFFOLK

Apricot Large Early.—Few growers can rely on Apricots for any length of time, the trees dying off so suddenly. The Moorpark is one of the worst in this respect. For some years I have grown Large Early, and find it little inferior to the Moorpark. It is also early, with free cropping qualities. This year I gathered the first fruit of this variety in the first week in August. I have both fan-trained and rider-trained trees. The latter I do not advise, as unless the wall is high the trees cannot be extended, and there is too much cutting of wood, which is not advisable. The Large Early makes a strong growth, and herein, I think, lies its value, as if we lose any shoots it is an easy matter to replace them with new growth. Unfortunately, one cannot always

get large trees owing to the demand, so that it is well to grow trees on for a year or two before placing in permanent positions.—G. W.

Pear Bishop's Thumb.—I am now sending this to table, and the fruit, though small, is juicy. It is an old variety and to some extent looked down on, but there are many worse than this. It certainly is not so fine-looking as many others, especially from old trees. My trees of it are old ones that for many years were kept spurred back closely, and consequently little if any fruit was produced. They have been allowed to have their head since then, all the pruning that has been done consisting in thinning out the branches and shoots entire where this was needed. The roots have not been touched. Struckering when the trees were spurred was very troublesome, but it has almost entirely disappeared.—H.

Compost for Muscat Grapes.—I fear many will not agree with the suggestion put forth at p. 416 regarding the compost for the above Grapes. I used to be under an excellent cultivator who was a great advocate of light borders, in the making of which he used sand liberally. Since that time I have had to do with diverse soils, and am not so much in favour of the too light ones. I think the important point is drainage, to which "N." at p. 416 refers. I do not think deep borders conducive to good Grapes, especially Muscats, and the best I ever grew were in 2½ feet deep borders. Many years ago we had not the various compounds now advised and much used, and so far I do not see that Grapes now a-days are any better than when grown without so much food.—S. H.

Peach A Bec.—We have no lack of good Peaches ripe in August, this variety being well worth room in all gardens where good fruits are needed. Requiring a great quantity of Peaches in July and early August, I find A Bec one of the most useful and reliable varieties. It is a large fruit, and I have found there is a great demand for large fruits if the quality is good. A Bec is of first-rate quality, having melting flesh and a peculiar sweet flavour not unlike that of a Strawberry. The fruits are of a rich crimson colour with a pale yellow tinge on the shaded side, the stone small for the size of fruit and separating freely from the flesh. I have it on a south-west wall, and this year the fruit was ripe on August 7. It is equally good in a cool house, coming in well after the forced kinds. It does not keep long when fully ripe, owing to its having a very thin skin.—S. H. M.

Plum Coe's Golden Drop.—This Plum of late has received more notice than usual in the pages of THE GARDEN, and it is well worth it, as, in my opinion, it is one of the most useful sorts grown, on account of its lateness and good quality. At p. 416 "C." says the fruits may be kept into November. In the north I frequently had this Plum for the dessert in December, and late pot trees gave the supply for Christmas Day. I do not know any other Plum superior to it for pot culture. The pot trees for the late supply named were kept under a high north wall to retard the bloom. This Plum may be kept from six weeks to two months if wrapped in tissue paper and then placed in a cool drawer or box. Though it shrivels badly, it is none the worse. My late fruits are from east and north walls, as here I find I get much finer fruits than when grown on standard trees, and they can then hang longer if netted. I find the fruit keeps much better if allowed to hang on the trees till the leaves have fallen, this in some seasons being late in October.—S. H. M.

Early pruning of fruit trees.—The early pruning of fruit trees has much to recommend it. When done before the new year it is seldom so cold as during the first three months in the new year, consequently it is got over much more quickly. Another advantage is that it can be done when other things are not so pressing. This is a method I have adopted during the last twenty-five years, having seen the advantage of so doing. Some thirty years ago, when serving in a good

garden in Buckinghamshire where there was a large number of wall trees, the pruning and nailing were commenced immediately the leaves fell, beginning with the Pears and Plums and finishing with the Peaches. Some think it is advantageous to leave the pruning of many things till the spring under the impression it retards the trees, but I have never seen any advantage from so doing. Last year I finished the pruning and nailing of the Apricots early in January, and no one could wish a better crop. This has been done for the last ten years, and I see no reason for a change.—DORSET.

PEACHES ON NORTH WALLS.

Few growers in the north would venture to plant the Peach on a northern aspect, and even in more favoured localities the trees at times may not always be quite satisfactory. On the other hand, when I grew trees thus, the crop on the north wall was a fair one when that in more favourable positions was poor indeed. The latter remark may be questioned by those who have poor soil and do not grow the Peach so well as desired, but the reason one crop fails where the other succeeds is owing to the trees on the colder aspect not being injured by frost; the bloom being so much later, the crop is often saved when the early bloom is injured. It is not worth while to plant a tree or trees if the soil is heavy and badly drained. Of course, such soil would not promote growth or ripen the same in the late summer months, but in a well-drained soil no one need fear evil results if the situation is favourable. There is a great gain in having Peaches for four or five months from open walls, and I am aware this may be accomplished even with trees on more suitable aspects if the kind of tree is studied. By planting a few midseason varieties on a north wall, if all points are favourable, one may have the best Peaches much later. Many owners of gardens who object to the poor flavour of the very late varieties and have a warm soil may with advantage adopt this system. I am not expressing these views entirely on my own experience, as only a few days ago I saw one of our most noted fruit growers lifting trees on a north aspect, and from these trees excellent crops had been secured. Here Royal George and Crimson Galande were the kinds most prized, and few varieties are of better quality than the old favourite; yet, strange to say, on a warmer aspect in some soils Royal George mildews badly, and many would hesitate to plant it on the colder site or position. I would not advise it only under the most favourable conditions. Crimson Galande is one of our best Peaches on walls other than the south, and such aspects appear to suit the trees well, as this fruit keeps well after gathering; indeed, in my opinion the quality is improved if the fruits are stored for a few days before using, as direct from the trees they are mealy if quite ripe. Dymond is a beautiful Peach, but should get the best culture. This grew grandly on an east wall, a very high one, being the back of a high fruit house, and grown on long stems or as standards, rider trained, there were grand fruits; but probably in anything but the best possible soil and locality Dymond would be a little risky, as it is later than the others named. Stirling Castle is good, as is Goshawk, as these make a good growth if the roots are in suitable soil. Grosse Mignonne as a standard trained on a high wall also did well, and was from three weeks to a month later than the same variety on a warm wall. It may be thought that a north wall would be better for the earliest kinds. I do not advise such, as there is too much risk; the trees flower too soon and are liable to be injured, as though later than on a warmer wall, the Peach flowering so early is not safe on the aspect named. G. W. S.

NOTES AND QUESTIONS.—FRUIT.

Pear Bourre St. Louis.—I found a tree here bearing the above name. In a warm, dry summer it

develops a colour such as I have not seen in any other Pear, but the exquisite rosy colouring on the sunny side with a golden ground belies itself when quality is looked for. In an ordinary summer it is not nearly so handsome. It ripens in the latter part of August and September, is of medium size, pyriform in shape, with a stout stalk of medium length.—W. S.

Peach Princess of Wales.—If the remarks of "Norwich" (p. 417) are read carefully, I fear there will be few growers of the same opinion concerning the above variety. I am aware as regards appearance, size, and good cropping no one can object to it, but its flavour, in my opinion, is very poor. It is largely grown for market and it always sells well, but in a private garden I would prefer Sea Eagle and the Neerarine Peach. In fruit catalogues Princess of Wales is strongly recommended, but my experience is that unless we get a very favourable season it is only second-rate.—S. B.

Pear Directeur Hardy.—This new variety fruited this season in sufficient quantity to test its quality. So far I have only grown it in cordon form and on a warm wall, so that in such a favourable position it received special culture. We have no lack of Pears in season at the time this one comes in, and many growers would have hailed it with delight had it been a March instead of an autumn variety. At the time of writing my fruits are quite ripe, but the light soil in which they were grown may have made them earlier. The quality is excellent and the tree crops very freely. Some pyramids on the Quince promise well and are covered with fruit-buds. I find there is always a demand for large Pears if the quality is good. Directeur Hardy will be an acquisition owing to its size, quality, and good cropping.—S. B.

DESTROYERS.

GOOSEBERRY BLIGHT.

(MICROSPHERIA GROSSULARIA.)

This fungus, according to a leaflet just issued by the Board of Agriculture, frequently causes many of the leaves of Gooseberry bushes to shrivel and fall off. Upon casual inspection of the bushes in the early stages of the disorder, the upper and under sides of the leaves look as if they were covered with white dust, or had been powdered with fine lime or sprayed with limewash. Under the microscope it is seen that there is a dense covering, which has been aptly termed a "felt-like coating," of slender white or greyish white threads on both sides of the leaves. These form the mycelium of the fungus, which does not, like the Potato fungus, live within the plant, but merely sends down short branches—sneakers or haustoria into the cells of the leaves. Upon these threads, or filaments, summer spores, or conidia, are first formed, which are borne by the wind from plant to plant and spread the disorder. Later on, the winter or resting spores are formed to carry the fungus on through the winter. These are imperceptible with the naked eye, but they may be seen with a glass late in July and during the autumn in the form of dark brown bodies upon the "felt-like coating." Upon examination of these bodies with the microscope they are seen to be nearly globular, with cross markings on their surface, and bearing from seven to eight slender, colourless filaments, with ends somewhat fantastically branched. It is supposed that these branched filaments keep the perithecia in place upon the mycelium on the leaves. The perithecia contain from four to eight asci, nearly oval cases, in each of which there are four or five spores. When the leaves fall the perithecia fall with them, and remain upon the ground or on the decaying leaves until the spring, when the asci burst, and the spores are liberated and speedily germinate in favourable conditions. An allied species of fungus causes very much more serious injury to Gooseberry bushes in the United States, so that it has lately been found almost impracticable to

grow there the finer varieties introduced from other countries. The appearance and life history of this fungus are very similar to those of the *Microspheria grossularia*, except that the former infects the fruit as well as the leaves.

PREVENTION AND REMEDIES.—The leaves from infested bushes should be raked from under and around them and burnt. The ground round the bushes should be dug or hoed deeply to bury the perithecia, and when the bushes are cut in the winter, every piece of cutting should be raked up and burnt. Any dead leaves remaining on infested trees should be, as far as possible, picked off and burnt. Where there is a sign of infection the leaves should be dusted thoroughly above and below with very finely powdered sulphur put carefully on with a knapsack powder distributor on a still, hot, sunny day. Sulphide of potassium diluted with water in the proportion of 1½ lbs. of sulphide to 50 gallons of water, and sprayed over and under the leaves in a fine spray, has been found to be efficacious. This dressing should be applied very early when the leaves are small and young, and should be repeated in about sixteen days. The Bordeaux mixture, as used for Potato disease, may be used with advantage—sprayed on by means of a knapsack sprayer in a very fine spray when the leaves are fully formed. The mixture should be made of 2 lbs. of sulphate of copper and 2 lbs. of lime to 25 gallons of water. If used later in the season, when the foliage is strong and fully developed, 3 lbs. of sulphate of copper and 3 lbs. of lime may be employed with 25 gallons of water. But care must be taken in the use of these applications when the leaves are young, also when the Gooseberries are large and intended for early picking.

THE BLACK CURRANT MITE.

For a long time the Black Currant has been considered one of the most profitable of small fruits by Kentish market growers, but whether this will be so in the future is open to doubt. A serious evil has presented itself, and one that is most difficult to overcome, in the form of the Black Currant bud mite (*Phytoptus ribis*). This troublesome pest, which is commonly known as "button bud," has totally destroyed more than one profitable plantation, and in the absence of any satisfactory means of eradication Currant growers are fearful for the future of this hitherto profitable crop. Growers of bushes that are affected would gladly make use of any practical means of clearing the pest, but, unfortunately, there does not appear to be sufficient known of the life-history and habits of the mite to be of any service. It is thought by some that the presence of the pest does not assert itself till the early spring, but in several plantations recently I have noticed numbers of swollen and distorted buds, which are due to the irritation caused by the feeding of the mites within.

As evidence of the serious increase of this pest, it may be stated that only a few years ago "big bud" was unknown among Kentish growers, and in many places it was not until it had made its injurious effect too apparent to escape unnoticed that much attention was paid to it. Only recently I was informed by a grower who has had to destroy several acres of Black Currants that he noticed the swelling of the buds at the outset, but paid no attention to it, as he thought it was early movement caused by the mild season. Bitter experience has taught him a different story, and after several attempts to get rid of the enemy he had to pull up and burn the whole of the bushes which for years had been a source of profit. Nor is this a solitary instance of the seriousness of the matter, and many growers who would like to plant Black Currants on a large scale are afraid to do so. Now a-lays in the

purchase of bushes the all-important question is whether they can be guaranteed free from "big bud," and it is more than likely that the rapid spread of the evil is due largely to planting infested stocks. Picking off the infested buds in the spring and thinning out the old wood in the autumn appear to be the best known means of keeping the foe in check. The cost of these operations is considerable, and I know of one large grower who this year has spent a considerable sum in having his bushes hand-picked. He is quite sure that if he had not followed this up persistently his plantations would now be valueless. I am not aware of the Currant bud mite asserting its presence in many private gardens, but the experience of other correspondents would not only be interesting, but something fresh might be gathered as to the mysterious pest which by its ravages not only affects the financial returns of Currant growers for market, but seriously threatens the future of what is now an important branch of a great industry.

G. H. H.

ORCHIDS.

ODONTOGLOSSUM TRIPUDIANS.

At this time of the year, when few of the yellow-flowered *Odontoglossums* are in bloom, the pretty arching spikes of *O. tripudians* are very welcome. There is considerable variation in the flowers, and some few are not particularly showy, but a really good form of it can hardly be beaten now among cool-house Orchids. In habit it is similar to *O. Pescatorei* and *O. crispum*, the spikes being produced in the same way. The type has chestnut-brown markings on a yellow ground colour, the lip pale yellow. A much deeper-coloured lip occurs in *O. t. xanthoglossum*, this organ being a pretty chrome-yellow, while another variety has a white lip with markings of bright rose. But it is singularly little grown considering how useful the flowers are, and one may go a long way and into many collections and not see a plant of it. The amateur or beginner will do well to add it to his collection at the first opportunity he has, and it is very interesting to obtain newly-imported specimens and see how they turn out as to variety. In selecting plants from an importation, regard must be had to their condition; but it is only fair to Orchid dealers of repute to say that in a far greater number of cases than formerly the plants are collected in better season, and this is to the advantage of everyone interested. Large or fairly large masses are greatly preferable to the small bits so often offered at sales in London and one or two provincial towns. They are practically worthless to nurserymen, and they are glad to get rid of them at any price. An *Odontoglossum* with half a dozen fair-sized pseudobulbs may often be worth more than a score of others with only about two on each, and the former if in fair condition should be selected. The process of plumping up the plants by laying out in a moist, warm house should never be neglected. Sometimes, of course, the plants will have been in this country some few weeks before being offered, and if so the owners will naturally have treated them as well as circumstances allow, so that when purchased they will be plump and possibly just about to emit roots. In this case they should be potted up at once. *O. tripudians* likes a moderate amount of compost only; anything like a thick layer must be at first studiously avoided. Unless root action seems imminent, the plants may simply be potted in clean pots, adding the peat and Moss when the roots begin to push. The plan of giving rather more warmth at

first to new importations has much to recommend it.

When well established and growing freely, *O. trijudians* is best in the coolest house with *O. crispum*, *O. triumphans*, and similar kinds, while the treatment is very similar. One difference is that often at the time *O. crispum* and others are being repotted, *O. trijudians* is throwing up its spikes, so that to disturb it would be unwise. It may in such a case be left until the late spring, or individual plants may be given new compost at the most suitable time according to the state of growth. For, although for all practical purposes *O. trijudians* may be considered an autumn-flowering kind, it is not at all unusual to see it blooming at various times throughout the spring and summer. The treatment must naturally be altered accordingly in such cases. The plant first flowered in this country in Mr. J. Day's collection at Tottenham in 1870, it having been introduced a short time previously by Messrs. Hugh Low and Co. It had, however, been known on the Continent for many years previously, having been sent to M. Linden's nursery probably by the Polish collector Warszewicz, who discovered it during his travels in South and Central America about 1850. It is a native of the rich *Odontoglossum* district about Venezuela and Colombia, whence it has been frequently imported. H.

Pleione maculata.—This is extremely pretty now, the finely fringed lip giving it a very delicate appearance. Some plants noted during the week growing in large pans were very bright and effective, but I do not consider them nearly so pretty grown in this way as when in small pots or pans that can be almost hidden by small Ferns or fine-foliaged plants. This is one of the best growers, like *P. lagenaria* in many respects, and may with advantage be repotted immediately the flowers are past. Afterwards keep it fairly dry until new roots are being freely produced.—H.

Spathoglottis Fortunei.—Though introduced by the Horticultural Society as far back as 1844, this species has never been very popular, and even now is not at all freely represented in collections. It was one of the plants found by Mr. Robert Fortune during his botanical exploration of China, and is a terrestrial species, thriving best in a cool intermediate temperature such as suits the Guatemalan *Odontoglossum*. The flowers are yellow, spotted with brownish red, and are produced in erect independent racemes. The best compost for it is equal parts of peat, leaf-mould, and Sphagnum Moss, in which it will grow rapidly and flower abundantly. Give plenty of water while growing, but after the flowers are past very little root moisture is needed.

Cattleya gigas.—It is surprising what a difference there is in plants of this species as to their freedom of flowering. To-day (November 28) I have been cutting the blooms from a plant that flowered in the summer and has now made another growth and bloomed again. The reason for cutting is that the growths are not quite so strong as usual. In the same house are plants that apparently will not flower with any degree of regularity, do what one will with them. There can be no doubt that, like *C. aurea* and one or two others, this fine *Cattleya* is better for resting after it has once flowered, but it is better to have it bloom twice than keep on growing without blooming, or only at long intervals. Still it is a question how long a plant will stand flowering twice in a season. I am afraid not long.—H. R.

Miltonia cuneata.—This is one of the most easily grown and generally useful of Miltonias, robust and free flowering, but not particularly constant in its time of blooming. From a light green ovate pseudo-bulb it throws up a tall spike containing about half a dozen or more flowers, each about 2 inches across. The sepals and petals are a dull chestnut, tipped and occasion-

ally lightly margined with yellow. The lip is white, lightly tinged with rose or purple spots. *M. cuneata* may be given fairly large and well-drained pots and a compost consisting of peat and Moss with a few lumps of crocks and charcoal. During the summer months it delights in being kept well up to the light in a very moist temperature, and need only be shaded from the brightest sunlight. Water the roots very freely, and even in winter they need never be dried. An intermediate house suits it best.

Camaridium ochroleucum.—This is a little-known species now-a-days, but a few years back I had several plants of it under my care. The growth is not unlike that of a *Cymbidium*, to which genus it is closely allied. The flowers are of medium size, having very narrow petals and broader sepals, these and the ground colour of the lip being a yellowish or greenish white, the latter prettily marked with brownish red. *C. ochroleucum* is an old garden Orchid, having been introduced from Trinidad as far back as 1823, and under cultivation it does well in a shady, moist part of the East India house during the period of active growth. When the growth is complete, a steady of the temperature is advisable, the bloom-spikes often appearing at the same time or only just before the young growth. The roots are fairly vigorous, and like a much more substantial compost than the majority of South American Orchids. The plants may be grown in teak baskets or pans.—H.

Lælia albida sulphurea.—This is a delicate and lovely form, but unfortunately difficult to do well for any length of time. The sepals and petals are a pretty shade of sulphur-yellow and the lip is paler than in the type, the front portion a pale rosy mauve. The growth is similar to that of the typical *L. albida*, and the plant may be grown at the coolest end of the Cattleya house during winter; in summer the lightest part of the *Odontoglossum* house suits it well. Where a house is set apart for these *Lælias*, it will be kept intermediate between the above, and makes a suitable place for this species. Very little is needed in the way of compost, and fine plants may be reared on flat or trellised blocks with only a little Sphagnum about them. The roots seem very partial to Moss if it is kept growing and not allowed to get too thick, but the fact cannot be lost sight of that, try how one will, there always will be some plants of this kind unsatisfactory. While growing, it needs abundance of moisture and a good clear light; while at rest the less water it has the better so that the bulbs do not shrivel.

MILTONIA ROEZLI.

This is one of the finest as well as one of the best known of Miltonias, and not being of the easiest culture, an exceptionally thriving lot of plants is always worth noting. Such a lot is now to be seen at Cambridge Lodge, Camberwell, where, from a very small batch of plants a couple of years ago, Mr. Chapman has now a fine bench full of beautiful little specimens, clean and vigorous, with that free look about them that anyone who has had experience with this class likes to see. Respecting autumn potting, the plants are an object lesson just now. Only repotted a very short time since, they are already rooting freely into the new material, and there is no doubt that with this Orchid, as with many more, stagnation is the worst foe to health and vigour. They must be kept moving, and, if repotting is necessary, they must be repotted. Thus small plants have a chance of pushing laterally, and larger ones produce abundance of side breaks, propagation by division explaining the rapid increase. For compost, good peat fibre and Sphagnum Moss are needed. The plants referred to are growing in a bed of Sphagnum, this, where repotting takes place, being about half way up the pots. During the season this, of course, grows very freely, and covers pots, and most of the compost, doubtless, providing in abundance the atmospheric moisture that these Orchids delight in. I have heard

amateurs who have a difficulty in obtaining supplies of Sphagnum Moss object to this mode of culture on the score of expense, but, as a matter of fact, there is a great saving in it, as one can always get a few nice green points for surfacing, and it is equally as good as Moss obtained direct from the bogs. It is better, in fact, for it does not need picking over, and, of course, injurious insects, as slugs and others, are not so liable to be introduced.

A brisk temperature and free exposure to light are necessary for *M. Roezli*, as it is known to be associated in its native places with such species as *Oncidium Kramerii* and other heat-loving kinds. But unless the heat is well tempered by abundant atmospheric moisture it is apt to bring insects in its train, and especially thrips, one of the very worst enemies to all this class of Miltonias, such as *M. vexillaria*, *M. Phalenopsis*, and others. It is useless trying to grow the plants if thrips are about them; consequently as soon as any signs of these appear the house must be fumigated at once, the fumigation being immediately followed by sponging. Both these operations must be well followed up until a clearance is made of the thrips. Many growers have a very careless method of sponging their plants, and this when an insecticide is used often leads to the surface Moss dying. The plants should first of all be dipped into clear, soft water, roots and all, this driving the insects out of the compost. Then dip the heads into the pail or tub of soft soap, or whatever is used—this and tobacco juice well diluted are the best for thrips. Go over the plants leaf by leaf after they have lain on their sides for a time to allow of the soap running away from the compost. If it runs down among the peat and Moss it encourages a troublesome fungus, especially when cheap foreign labels are used. The neat little disc labels now often used are so effective and cheap that it is surprising the older and clumsy method is so much in vogue. Besides the type with white blossoms and a purple centre, there is a pretty albino form of *M. Roezli*, this being now fairly plentiful. The species is named in compliment to its discoverer, M. B. Roetzli, who is said to have first met with it a long way from its habitat, floating down one of the swift mountain streams in New Grenada attached to its native tree. A few years afterwards it was discovered and sent home by other collectors, and is now plentiful. H.

Catasetum callosum.—This is a quaint-looking species of very unusual colour, and quite distinct in its peculiar gradations of pink, brown, and emerald-green. Like others in this genus, it is of very remarkable form. The plant is not particularly difficult to grow. During the growing season it likes a moist, warm house, and should be kept well up to the light. After flowering, until growth again starts, it may be kept quite dry in an intermediate temperature.

Cœlogyne barbata.—Flowering before the varieties of *C. cristata*, and keeping up a display over a considerable time, this *Cœlogyne* is worth a place in all collections. The plant is not at all difficult to grow, liking an intermediate or cool Cattleya house temperature and a shady moist position. The growth is vigorous, and the roots delight in a rough, open compost in which the ingredients are kept well apart, and a little leaf-soil mixed with the usual peat and Moss is a good addition. Plenty of water is needed while growing freely, and no drying off need be practised.

Masdevallia macrura.—I have noted this fine species in flower during the week, and it is certainly one of the best of all *Masdevallias*. The tube formed by the sepals is tawny yellow, the open portion covered with purple spots, the tail yellow. Being so strong in growth, it is, perhaps, as easy to grow as any *Masdevallia*, and may be cultivated in rather larger pots than usual, these being filled with rough, open compost kept always very sweet and open. It thrives in the cool house, needing plenty of water all the year round. It is a native of New Grenada, and was sent home to Mr. Bull by one of his collectors in 1876.—H. R.

LÆLIO-CATTLEYA DOMINIANA AND
ITS VARIETIES.

THIS, the last of the twenty-five hybrids raised by Mr. Dominy, flowered for the first time in 1878, and was described by Reichenbach as *Lælia Dominiana*. For its richness of colour it surpasses all of that raiser's productions. This and the recently-raised forms, which have proved the doubtful parentage that originally existed, are without doubt the finest of the hybrids of the Cattleya family that have yet been seen. The two original plants have for many years formed unique specimens in the collection of Baron Schröder, The Dell, Egham. There is no record of the original plant having been exhibited, but the variety *L.-C. Dominiana rosea* was awarded a first-class certificate by the Orchid committee of the Royal Horticultural Society on June 24, 1884. A full description of the plant was given in THE GARDEN report of that meeting. The second to raise this cross

long remained with regard to parentage. The subject of the accompanying illustration, *L.-C. Dominiana langleyensis*, was raised by Mr. Seden, and is the result of crossing *Lælia purpurata* and *C. Dowiana*. It was exhibited at the Drill Hall meeting of the Royal Horticultural Society on October 11 last, when it was awarded a first-class certificate. As a variety it is certainly distinct from any of the forms previously seen, and is by no means inferior to them. Like most other hybrids where considerable variation exists among the parents, the offspring naturally retains the variable characteristics, which no doubt account for the distinctive features seen in the subjects of this note. There is perhaps no species of the Cattleya family that is more variable than *Lælia purpurata*. In *L.-C. D. langleyensis* the sepals are pale rose, mottled with white, the petals pale rose, suffused with a darker shade, the broad, finely-shaped lip deep crimson-purple, with a darker shade of crimson in the centre.

paintings of the certificated flowers something might be done to prevent such occurrences in the future. Owners of plants also might assist by consulting one or other of the numerous lists of hybrids that have been published before naming any of their seedlings. C. J. H.

Lycaste lanipes.—Though one of the least showy of the Lycastes, this species is pretty and well worth growing. It is very free-flowering, the individual blossoms about 4 inches across, the sepals greenish white, the petals pure white, the lip white and prettily fringed. Grow it in a cool, moist house in a compost consisting of equal parts of peat fibre, loam and chopped Sphagnum Moss. Water must be freely applied all the year round, especially while the growth is most active. Light sprinkling overhead is of great assistance in hot weather, keeping the foliage cool and moist and preventing insect attacks.

Cœlia macrostachya.—This species is not much grown, but the pretty feathery spikes of bright rose flowers, each with its attendant silvery bract, make it quite worth a place. A fine plant now in flower has half a dozen spikes, and against the deep green foliage they have a very pretty effect. It is an easily-grown kind, but will not flower satisfactorily unless the plant is allowed to rest naturally. I stand it in a cool Peach house when the growth is complete, and when again placed in a little warmth towards autumn, the stiff scaly spikes soon make their appearance. It is strong growing and likes a fairly large pot and a sound, open description of compost.—H.

Maxillaria picta.—When well grown and flowered this old species is certainly worth a place if only for its distinctness. The peculiar combinations of yellow and purple with red are not to be seen in any other kind, and the flowers have the additional advantage of being very long-lasting. *M. picta* makes the best growth in a temperature slightly lower than that of the Cattleya house. The growth must be shaded from bright sunshine, and the plants may be potted in equal parts of peat fibre, loam, and chopped Moss. Damp the leaves lightly overhead in the growing season.

Cypripedium niveum.—The blossoms of this species, though small, are extremely pretty and interesting, the pure white of the segments when seen at a little distance showing up well against the mottled foliage. A closer view reveals the spotting, and this is also delicate and pretty. A native of Siam, it delights in ample warmth, and though shade is undoubtedly necessary, it thrives admirably when grown in small pans and kept well up to the light. A few bits of limestone may be mixed with the compost, which must also contain a little light loam. Drain the pans well, and if not particularly well rooted, keep the plants up a little in them and water carefully all the year.

Oncidium crispum.—This fine autumn-flowering *Oncidium* is still in good condition, and I have noted it on several occasions flowering finely. Keeping the spikes on plants that are expected to do well greatly distresses them unless really strong and well established. Grown on rafts or in baskets not far from the roof glass in an intermediate house, this plant grows and attains more strength annually, though allowed to flower, provided the spikes are removed after

Lælio-Cattleya Dominiana langleyensis. From a photograph by Mr. J. Gregory, Croydon.

was Mr. F. Hardy, of Tyntesfield, near Manchester, who sold part of his plant to Mr. G. W. Law-Schofield, who exhibited his plant at the Temple show of 1897, when it received a first-class certificate as *L.-C. tyntesfieldensis*. The parentage was unknown, but little doubt existed that it was a form of *L.-C. Dominiana*. THE GARDEN report of the above certificated plant gives the required details. *L.-C. Apollonia*, raised by Mr. J. Douglas, was exhibited on November 24, 1896, when it received an award of merit. I have recently seen this plant in flower. It is a most distinct and handsome variety, the sepals and petals being rose, beautifully mottled with white; the lip rich velvety crimson in front, the side lobes lighter and thickly lined throughout with yellow and white lines. The intermediate characteristics of the two parents are so pronounced, that little doubt now remains as to its origin.

It has been left for Messrs. J. Veitch and Sons to clear up the uncertainty which has so

The outer edges are beautifully corrugated and margined with rose, the side lobes crimson, suffused with brown at the base, where it is thickly covered with bright yellow lines. The flowers on a four-flowered raceme were fine in substance and in form. It is certainly one of the best hybrids that has ever been raised.

Now that the parentage has at last been defined, it is to be hoped that the original name of *L.-C. Dominiana* may be adopted, and all the above-mentioned which have been certificated, classed as varieties only. The plurality of names in the nomenclature of hybrids is most confusing. The Orchid committee of the Royal Horticultural Society cannot claim to be blameless in this matter. They have their rules for guidance, but I am sorry to say they have been obeyed more in the breach than in the observance. Seedlings from crosses that have been previously recognised have been in some instances certificated four or five times over. Surely with careful records and the

a reasonable time. Very little compost is needed, as the roots are easily injured by anything sour or close.—H.

LATE-FLOWERING LÆLIO-CATTLEYAS.

THERE is not a more interesting or useful class of hybrids of the Cattleya family than those which flower during the autumn months. This section of late years has been considerably increased by the introduction of many beautiful forms, which have almost entirely filled up the time between the late summer and autumn, and help to keep up a continuous succession of Cattleya bloom throughout the year. From *Lælia Perrini* the late-flowering hybrids have mostly been derived. These flower through the months of October, November, and December. A note on the best of these may be interesting, and as they are now within the reach of most Orchid growers, they should be much more extensively grown.

LÆLIO-CATTLEYA LADY ROTHSCHILD is, perhaps, the best of the group. It is the result of intercrossing *L. Perrini* and *C. Warscewiczii* (*C. gigas*). The sepals are almost white, having a slight suffusion of rose, the petals darker than the sepals, the lip rich crimson-purple, with the yellow eye as seen in the pollen parent. The side lobes are rose, with some yellow lines towards the base. The flowers are of fine form and substance. It was raised in Messrs. J. Veitch and Sons' nurseries, where I recently noted it coming into flower.

L.-C. DECIA is an interesting and useful hybrid, the result of intercrossing *L. Perrini* and *C. Dowiana aurea*. It has the intermediate characters of these species both in habit of growth and in the flowers. The sepals and petals are rose, mottled with creamy white, the ground colour of the lip rose, suffused with crimson-purple on the front lobe. The side lobes are open, the ground colour rose-purple, thickly covered with numerous longitudinal yellow lines.

L.-C. STATTERIANA is the result of crossing *L. Perrini* and *C. labiata autumnalis*. It is one of the most distinct and beautiful of the intermediate-sized Cattleya hybrids. The two parents are remarkably blended in the flowers. The sepals and petals are bright rose, of fine form and substance; the front lobe of the lip rich velvety crimson, becoming lighter at the base, and through the throat it has several light yellowish lines.

L.-C. SEMIRAMIS (*L. Perrini* × *C. Gaskelliana*) flowers earlier than the above-mentioned hybrids, and is perhaps the finest shaped flower of the section, but is not so beautifully marked on the lip as some of the others. The sepals are of fine form and substance, rich rose-lilac, the front lobe of the lip crimson-purple, the side lobes rose with some yellow at the base. It has the intermediate characteristics both in the habit of growth and in the flowers. STELIS.

LÆLIA ACUMINATA.

A good form of this species is well worth growing, as it is quite distinct from the other Mexican species. The flowers are variable in colour and several varieties are known, but that usually considered the typical form has very pale rosy blossoms, produced on semi-erect spikes about half a dozen on each. The lip is stained with yellow, and has a deep maroon blotch in front of the column. Being of dwarf habit the plants do not care for a large receptacle or a close, heavy body of compost, and rafts suit them as well as anything. Baskets almost filled with crocks and surfaced only with peat and Moss are also suitable, and I have seen it doing well on blocks of rough Apple or Pear wood, the bark being left on. The only fault of the latter plan is that insects of various kinds find in the bark congenial quarters, otherwise the natural roughness suits

the roots well. In placing the plants on these blocks, a little Moss may be put round the base of the bulbs with advantage, as it serves to keep a little moisture about them, but when they are well established the bark alone is sufficient to keep them right if frequently dipped. They like, in fact, to be dry for an hour or two almost daily, and afterwards to be thoroughly saturated with moisture, the water being used in a tepid state. All through the growing season the roots may be very freely watered, daily attention being needed if the latter plan is followed, as, owing to the free supplies of air, they dry rapidly. Besides this, the sun may be allowed to shine almost directly upon the plants, the leaves being of that leathery, hard texture that will stand plenty of light. Only in the height of summer weather is shading necessary, and this only in the middle of the day. This is, of course, when the *Lælias* themselves are considered; when other plants are grown in the same house their wants have also to be studied. During winter much less, of course, is needed, and as long as the pseudo-bulbs keep plump no harm will come to the plants. The temperature in winter will not need to be high, a night temperature of 55° being ample, and a few degrees less will suffice in cold weather. In summer the sun will naturally raise it rather high, and this will do no harm provided free ventilation is allowed. Overhead watering is not required, and if in the least overdone, the water is apt to gather at the centre of growth, this often leading to damping of the spikes in autumn. The plant is somewhat widely distributed over Guatemala and Mexico, but not so frequently imported as the other Mexican kinds, so probably it is scarce there. It was first flowered by Mr. Barker, of Birmingham, about 1841, when it was described by Dr. Lindley. H.

Odontoglossum Cervantesi membranaceum.—Though no larger in growth than the type, this variety produces much finer flowers and is certainly more difficult to grow. In a small importation from Guatemala a few years since I flowered one or two plants of this variety, but have never been able to do much with them, though the type form thrives in the same house and under the same conditions. Whether the fact of its usually occurring further south has anything to do with it or not, I cannot say, but it does no better with increased warmth. These small-growing kinds are very easily checked by mistakes in ventilation or by sudden changes in temperature, and the best way to grow them is suspended in small pans or baskets within a few inches of the roof glass. Here they get the full benefit of the air currents and are not, as a rule, exposed to direct draughts, while the light plays freely about them during dull wintry weather. The roots should be kept moist all the year round, any drying off being followed by shrivelled bulbs and weak growths.—H. R.

Oncidium cheiroporum.—It would be difficult to name a prettier or more useful cool house *Oncidium* than this. The plants can be bought at a fairly cheap rate; they are easily grown and flower most abundantly. In habit the species is dwarf, the pseudo-bulbs only about an inch high, the whole plant with flower-spikes seldom exceeding a foot. The colour of the flowers is a clear bright yellow, always a favourite tint for winter decorations. *O. cheiroporum* should be planted in small pans or pots in a compost of about equal parts of peat and Sphagnum Moss over good drainage, and this may be raised on a slight cone and carefully and neatly clipped off. It does well in a house devoted to such plants as *Odontoglossum grande* or *O. citrosum*, but if no such one is at command, it does very well with quite the coolest section. It is an admirable little species for finishing off the front of a group

of flowering Orchids, being dwarf, light and elegant. It makes better and larger specimens if several plants are massed together in a pot or pan, though here care is especially necessary in watering during the winter. Keep it at the warmest and lightest end of the house to consolidate the little bulbs and keep the water supply going until these are quite made up.

Cattleya Holfordii.—Excepting in name, this differs little, if any, from the old and little-known *C. luteola*, and the flowers to hand from "*C. C.*" are those of an entirely different species—*C. velutina*. The largest flowers of Holfordii are not more than 2 inches across, bright yellow on all the segments, the lip having a margin of white and radiating lines of crimson-purple to the side lobes. In habit it is perhaps the dwarfest of the true Cattleyas, seldom exceeding 6 inches in height, and the short flower-spikes usually carry about three or four blooms. Such a plant will naturally require treatment somewhat different from that given to those stronger-growing kinds, such as the *labiata* group, and though coming from the same regions, will not stand the same extremes of heat and cold or so much sunlight. I have been most successful with it in a house where *Pescatoreas* and *Warscewiczellas* flourish, that is in a slightly higher and moister temperature than the Cattleya house proper and with considerably more shade. Here it rests but little, and often makes a couple of sets of growth in one season, flowering most regularly upon the stems made during the summer and autumn months. The plants may be grown in equal parts of peat fibre and Moss in suspended pans, the limited size of these receptacles suiting the roots well. The plants also do well in baskets, but if these are used they should be wide rather than deep and thoroughly drained. *C. luteola* (*Holfordii*) comes from the upper regions drained by the Amazon, and appears to have been first grown in this country in the York nurseries, where it flowered about 1853.—H.

FLOWER GARDEN.

PRIMULA CAPITATA OUTDOORS.

THERE are more than forty species of Himalayan Primrose described in "*British Herbaria*," but not more than half a dozen of them are truly hardy and capable of taking care of themselves in the open air through English winters and summers. A few others are grown in an intermittent sort of way with the help of a greenhouse or frame, but the larger portion seem unwilling to adapt themselves to any conditions yet tried in cultivation, even if worth the trouble of cultivating. In mentioning *P. capitata* (Hooker) I speak entirely from my own experience, having had it annually flowering in large quantities in my garden in Cheshire for about twenty years. Still, I have always found it troublesome and wayward, and it is not truly hardy. It is found wild on the Himalayas of Sikkim at elevations of about 15,000 feet, and I have once or twice raised it from seed collected wild, and distributed either from Kew or from the Calcutta Botanic Gardens; but nearly all my raisings have been from seed collected in my own garden. Though it seems perennial by nature, its habit with me is biennial, that is to say, it flowers the second year and never survives a winter after flowering. Its life history at Edge is as follows: Seed is sown under glass as soon as ripe—about the beginning of September. It comes up abundantly and is kept growing on in a cool frame, just free from frost, all winter. At the end of winter it is pricked off into wooden trays 4 inches deep, perhaps fifty in each tray, and kept growing in the cold frame till May, when the whole tray is turned out and planted

where it is to flower, without disturbing the soil. The soil is fine sandy loam and the situation sheltered, raised beds, sloping either to the east or north, but, provided plenty of water is given

of the Royal Horticultural Society," vol. iii., p. 211. It is referred to by the gardening press of the time as one of the bedding plants of the future, and one which no one would consider unsatisfactory. Looking at it from the experience of the fifty years which have elapsed since its introduction, we are amused to read the confident words of an eminent horticultural writer of that day: "I shall pledge my word, however, that no one who will buy the two plants that I shall name to-day will ever feel a disappointment respecting them." The "two plants" were *Plumbago Larpentæ* and *Zauschneria californica*. As a flowering plant in the generality of gardens, *Z. californica* is a decided disappointment.

In cool parts of these islands it rarely flowers, but one was rather surprised to observe, from a recent note in THE GARDEN, that a Cornish correspondent found it very unsatisfactory also. One would have thought that this Californian *Fuchsia* would have found a warm enough climate in southern a latitude. It would be rather interesting were those who succeed in flowering this *Zauschneria* regularly to compare notes with those who count it among their failures, not that it is easily lost, but because of its objection to opening its flowers in many gardens. I can speak of it with painful experience, as for ten or more years I have been hoping against hope and seeking in the most likely places I could think of to persuade my plants to flower. I have asked and have been asked many questions about its conduct in gardens, and grieve to say that in the vast majority of instances nothing but a tale of disappointment has been to tell. Buds appear giving promise of flowers, but the promises prove illusory and the buds drop off ere they can open.

It is much to be regretted that one can only speak in so hopeless a strain of this *Zauschneria*.

The answer is surely a sufficient one. The plant is regularly offered for sale; its colour, character, and time of flower are all attractive to read of. One can only hope that a timely warning may induce some who think of growing this plant to leave it alone and content themselves with something which will annually return by wealth of flower a recompense for the space and care it requires. S. ARNOTT.

Carslhorn, by Dumfries, N.B.

CARNATION COUNTESS OF PARIS.

THE stock from which this bed of Carnation originated consisted of three plants of *Meta* and two of *Comtesse of Paris*. They were weak layers, planted after the middle of November, 1895. During the early part of August, 1896 and 1897, every shoot available was layered into a compost of burnt refuse, leaf-soil and plenty of sand. The soil is a poor sandy loam, nearly all sand. It received a light dressing of manure and burnt refuse and a slight dusting of soot to prevent worms disturbing the newly-planted layers. In 1897 the layers were planted on October 4, and had no dressing or stimulant of any kind. They received a heavy watering two or three times while the buds were swelling. This culture is practised here with all varieties of border Carnations. All are planted as early as possible in autumn. They are never grown on the same ground more than two years together. Probably the success I have had with Carnations may be attributed to early layering and firm and early planting on fresh, sweet ground. They receive no protection of any sort. K. C.

Sowing Sweet Peas in autumn.—It is now upwards of forty years since I first saw Sweet Peas sown in autumn. They nearly always do well, and commence flowering from the middle of May. At present I have a row sown in the open quarter just coming through the ground. The one protection they require through the winter is the soil drawn up on each side of them. Should birds be troublesome, protect with Pea guards.—RICHARD NISBET, *Market Drayton*.

Tropæolum Lobbianum.—I have seen nothing prettier this summer than a house covered on one side with this *Tropæolum*. The plants were trained on a trellis fixed to the house,

Primula capitata. From a photograph by Miss Dod, Edge Hall, Malpas, Cheshire.

through summer, aspect matters little. The flowering begins towards the end of July and continues till a hard frost checks further growth, perhaps late in October, successive umbels being thrown up until, at the end of the season, a good plant will have seven or eight umbels in various stages of development. A dry summer is an abomination to this species, and causes many of the stock to wither up, as no watering is as good as showery weather and damp atmosphere from a rainy quarter. The roots are remarkably thin and frail, and a very little force, even a high wind, breaks away the top from its hold in the ground. No attempt is ever made by *P. capitata* to form a winter bud, such as is made by *P. denticulata*, *P. rosea*, *P. farinosa*, and *P. sikkimensis*, four of the most easily cultivated Himalayan kinds. The leaves of this in many cases continue green and horizontal to the end of winter, but sooner or later the whole tuft breaks away from the roots before any spring growth commences. Now and then I notice one or two self-sown seedlings where a clump has been grown; these come up in spring or summer and live through winter and grow on, but I do not observe that they flower any earlier than those sown under glass in autumn. C. WOLLEY-DOD.

Edge Hall, Malpas.

ZAUSCHNERIA CALIFORNICA.

WRITING in THE GARDEN some time ago about *Plumbago Larpentæ*, I referred to the exaggerated expectations entertained of its success in British gardens. Of a plant introduced about the same time, but from the New World instead of from China, one has occasion to remark that equally roseate views were held of its future value in the garden. This plant is *Zauschneria californica*, seeds of which collected by Hartweg near Santa Cruz, California, were introduced into this country in 1847, the plant being spoken of in the "Journal

Carnation Countess of Paris. From a photograph sent by Miss Katherine Corbett, Nantwich, Cheshire.

Its *Fuchsia* like scarlet flowers would be a gain to our borders and rock gardens could we persuade them to come yearly to please us. It may be said by the reader, *en bono*: If we cannot tell how it may be flowered, why speak of it at all?

and were so late as the middle of November a mass of bloom, which forcibly illustrates the abnormal mildness of the autumn, for in a general way tender things are in this part of Surrey cut off by the middle of October, and not infrequently

much earlier. There is something very attractive about *T. Lobbianum*, the deep green foliage, which is by no means coarse, contrasting finely with the glowing tint of the flowers. When this variety is used in the open air, it should be set out in tolerably rich ground, as it does not go away with such freedom as the common *Nasturtium*, and in poor soil is apt to become stunted. For covering a trellis, for window boxes or for planting in conservatories this *Tropeolum* is one of the most useful things one can employ, the immunity which it enjoys from insect pests being a great point in its favour.—J. C. B.

NOTES ON HARDY PLANTS.

Selaginella denticulata.—With regard to the hardness of this I have had a long experience, and yet in every case of a special planting it has failed to live through a winter, whereas bits that have found their way into the garden or garden walks from greenhouse plants that were being stood outside in the summer have often grown and lived through the winter. In one place especially sheltered from N. and E., and where the soil was more like gravel, I have always been able to find healthy pieces. In speaking of a plant of this kind I would always make a point of observation of difference between specimens that seem fresh and green in March and those that may remain healthy and make new and vigorous growth in summer, because it is often that reputedly hardy succulent species may seem promising in early spring and then die off suddenly. My experience with this plant has been both ways in the same season, and so it seems to me that other conditions besides those of the weather have something to do with the hardy culture, and because I have always found the healthier plants in spring to have self-selected positions, those invariably in the garden walks or loose plunging material, as ashes, sand, or burnt clay. I think the crucial point of culture may be sought in the rooting medium. I am not confounding *S. helvetica*, another and perhaps more hardy species, with *S. denticulata*, though I believe when both are grown out of doors they more nearly resemble each other than when compared, as they more often may be, the former from the open and the latter from a greenhouse, and it is precisely because of the improved and pretty habit of *S. denticulata* when grown out of doors that it may be worth establishing as a hardy plant. To start it perhaps there can be no better way than to stand in garden walks old fruiting plants of it from the greenhouse in early summer. The spores soon germinate and dot the surface with green quite as freely as *Marchantia*; at least, it is so here. *Marchantia* with me is a pest, while in many gardens it cannot be induced to grow. May not these unknown conditions have some influence on *Selaginellas*?

Primula capitata.—By this I mean the true *P. capitata*, and not the variety of *denticulata* sometimes so-called. This is almost the only thing here that can be said to yet have fresh flowers, so that for a species which blooms so long it claims a more than passing note.

Colchicums not flowering.—It does not seem to be generally known why these fail to flower abundantly. I say abundantly, because I take it that all the *Colchicums* are free bloomers, and yet like nearly everything else their habit needs to be qualified, especially when in a garden of deep rich soil. Perhaps the deeper and richer the soil the fewer the seasons of plenteous flowers in succession. It happens in this way: Every year the corms or tubers make a bound deeper, so to speak, until they get so far from the surface as to get less vigorous. This can be proved by anyone who has old clumps. If dug up they will be found at a far greater depth than ever they were set or anyone imagining they ought to be set, and the bulbs much deteriorated in size. My practice is to lift every third year any kinds I consider worth the trouble, and the effect the first year is most remarkable; not, of course, in getting more flowers the first year, as that could

not be, but in the extra size that the tubers attain from being brought up to, say, within 2 inches or 3 inches of the surface in fresh soil. The following year the flowers are as abundant as the most sanguine could ever expect. All this is not prophecy, but the simple results of many years' practice.

Two handsome fruiting creepers of a dwarf habit, and in the last month of the year to be seen in the rock garden to advantage, are *Vaccinium Vitis Idea majus* and *Gaultheria procumbens*. In both cases the evergreen foliage with the blended warm tints of brown and red may be reckoned upon to produce a good winter aspect for rock gardens. J. Wood.

Woodrille, Kirkstall.

WINTER MULCHING OF PERENNIALS.

ALTHOUGH all those inmates of our gardens known as hardy plants or perennials will come safely through the majority of winters, there are exceptional seasons when some of them will either be killed outright or so mutilated that they do little good the following year, and so it is well to be on the safe side, and if there is a suspicion as to the hardness, to place a good thick mulching about the crowns not later than the first week in December. I was never, for instance, in the habit of giving any protection to outdoor Fuchsias, but, having lost many in the very severe season some four or five years ago, have always practised it since. Where stools of these have remained in the same situation for several years and the central parts are gone, or there is a tendency to weakly growth, they should be lifted at the present time and the strongest bits replanted, placing the mulching about them as soon as this is effected. I have always mulched my clumps of *Gypsophila*, and so am unable to say if this is perfectly hardy or no. One or two bits that escaped notice perished in the winter that proved fatal to the Fuchsias. Where *Montbretias* have been late lifted and replanted, I should not advise present mulching, as a spell of cold keeps the young growth in check whilst yet under the ground, but when this makes its appearance in the early year after a spell of warmer weather and cold again follows, a mulch is very beneficial if early flowering is required. Once planted in any particular spot, the annual reappearance of *Nicotiana affinis* can be guaranteed by the aid of a thick winter covering. I find, on the other hand, it is always destroyed if frost penetrates to the fleshy roots. The desirability of annual lifting or non-lifting of the varieties of perennial *Lobelia* has often been discussed, and from the various notes it would appear that it is more a question of situation and atmospheric influence than danger from frost. I have never lifted except when the stock had to be increased; this has always been replanted in autumn and a thick winter mulching invariably applied. So far as those popular inmates of the garden, Carnations and Tufted Pansies, are concerned, there is not the slightest reason to suppose that a winter covering of the ground is necessary as a protective agency. It is, however, necessary, if not absolutely essential, in securing good results on all light soils, as the rains of winter are thereby retained, and the additional moisture with the slight stimulant afforded by the manure is highly beneficial. Other forms of mulching that often have to be considered if the stock of perennials is large and varied are a liberal covering of rather rough ashes about and around the young growths of plants for which slugs have a decided partiality, and in the case

of early flowering bulbs protecting the foliage and buds to partially anticipate the opening of the flowers. E. BURRELL.

CHRYSANTHEMUMS.

NEW JAPANESE CHRYSANTHEMUMS.

AS usual the number of novelties this year is enormous, and the difficulty of selection must be exceedingly great to those growers who have not the opportunity of visiting personally the various floral meetings and the trade displays. After having paid visits to a great many places, I have come to the conclusion that the best exhibition novelties for next year will be found in the following selection, viz. :—

MISS MARY UNDERHAY.—This ought to become a favourite, as it is one of the best of the Japanese incurved type that has been raised in the colonies. The florets are of medium width, grooved, and of good substance. The colour is a rich, clear shade of pure yellow.

MRS. ERNEST CARTER, Japanese, has long drooping florets, very closely arranged. The colour is a very delicate shade of clear, deep primrose-yellow.

LORD CROMER, Japanese, has long, medium-sized recurving florets, blooms large; colour rich velvety reddish crimson, very dazzling in tone, reverse golden.

MRS. W. MEASE is the finest of the Carnot family; a lovely pale shade of primrose or sulphur-yellow.

MRS. WHITE POPHAM.—Very large incurved Japanese, with broad, grooved, pointed florets; colour pale purple-mauve.

LADY PHILLIPS.—A bold incurving Japanese, big and solid in build, very broad florets; colour pale mauve, reverse silvery pink.

PRESIDENT BEVAN.—Japanese incurved, a fine closely built flower, with sharp-pointed florets, deeply grooved; deep yellow, shaded bronze.

MME. COUAT DE TERRAIL.—Japanese; the florets are long, twisted somewhat after the Good Gracious type; colour white, tinted in the centre.

LE GRAND DRAGON.—Japanese; large blooms, with long drooping florets of medium width; colour rich deep golden yellow.

MISS NELLIE POCKETT.—Japanese of colonial origin, with very narrow grooved florets, incurving and pointed at the tips; a closely built flower; colour pure glistening white.

CHATSWORTH.—A Japanese from the same source as the preceding. It has long, narrow, drooping florets forming a very deep flower; colour white, streaked with pinkish purple.

PURPLE EMPEROR.—A very fine deep type of Japanese, but not over large; the florets are of medium width and grooved. The colour is a velvety shade of plum-coloured amaranth with a reverse of silver. Also a colonial.

MR. T. CARRINGTON.—A worthy companion to such flowers as *Pride of Madford* and *Australie*, to both of which it bears a family likeness. It is a massive Japanese incurved, with long florets of medium width, grooved and pointed at the tips; colour deep bright purple, reverse silvery pink. Another colonial.

JANE MOLYNEUX.—A large Japanese with very long florets; a flower of great depth; colour creamy white.

SIR HERBERT KITCHENER.—Another gigantic Japanese with florets of medium width, long and drooping; colour rich shade of golden chestnut, reverse golden.

MISS MARY LESCHELLES.—A very pure white sport from *Reine d'Angleterre*, which it resembles in every respect save the colour.

EMILY TOWERS.—Japanese, with medium-sized florets, incurving in the centre; colour rosy lilac-mauve, reverse silvery pink.

R. HOOPER PEARSON.—A Japanese of colossal dimensions, with rather broad florets, curly at

the tips; colour very rich shade of golden yellow, with paler reverse.

MRS. COMBE.—Japanese; florets long and drooping, blooms large, very full and double; colour deep rosy mauve.

C. HARMAN-PAYNE.

AUSTRALIAN CHRYSANTHEMUMS.

It is now some few years ago since I first drew attention in the columns of THE GARDEN to the progress that was being made in Australia and New Zealand in the raising of new seedling Chrysanthemums there. It was also only natural to suppose that these novelties would in due course be imported into England, and it is interesting to record that during the present season large numbers of them have been seen in very good condition at most of our trade displays.

The following list is compiled from notes made from those blooms that have been seen in the best condition, and the record is, I think, a valuable and interesting testimony to the skill of our colonial colleagues:—

WONDERFUL.—A Japanese incurved of the Wheeler type, with broad florets; colour velvety purple-crimson with straw reverse.

J. BIDENOPE, if not actually of Australian origin, is, at any rate named after an Australian grower. It is a purple-amaranth Japanese, with silvery reverse.

MRS. BISSETT.—A Japanese, the florets slightly incurving; colour white, slightly tinted.

G. KERSLAKE, JUN. has very long florets. It is a Japanese, the colour white.

MISS VERA MAY FRASER.—A Japanese incurved, with broad grooved florets; colour a very fine shade of warm terra-cotta, reverse golden.

MASTER H. TUCKER.—Japanese; colour deep velvety bright crimson, reverse golden.

OCEANA.—A well-known yellow.

MISS NELLIE POCKETT.—Very pretty Japanese with very narrow incurving florets, grooved and pointed at the tips; colour pure glistening white.

JOHN POCKETT.—A deeply built Japanese incurved, with rather broad florets of a very rich shade of deep golden bronze or chestnut, reverse gold.

PRIDE OF MADFORD is too well known to need description.

AUSTRALIE.—The same remarks apply to this one.

PRIDE OF STOKELL.—A sport from Pride of Madford, in colour a deep velvety crimson with golden reverse.

MABEL KERSLAKE is probably a synonym of the preceding, being a crimson sport from Pride of Madford.

AUSTRALIAN BELLE.—A Japanese, with very long tubular florets; colour deep rosy pink.

MRS. C. BAWN.—A Japanese of good size; colour white.

PURPLE EMPEROR.—A very finely formed, deep, compact flower of the Japanese type, florets medium sized and grooved. The colour is a beautiful velvety shade of plum-coloured purple, reverse silvery.

CHATSWORTH.—A Japanese, with very long, narrow drooping florets forming a deeply built flower; colour white, streaked pinkish purple.

MR. T. CARRINGTON.—A worthy companion to Australia and Pride of Madford. It is a Japanese incurved with long, medium-sized florets, grooved and pointed; colour deep bright purple, reverse silvery pink.

THE CONVENTION.—Japanese incurved with long pointed florets; a globular flower; colour deep golden terra-cotta lined with bronze inside.

MRS. G. A. HAINES.—A Japanese, with rather small, broad incurving florets; colour golden bronze, reverse gold.

MRS. J. T. THIBBS.—A white sport from Lillian B. Bird, raised in New Zealand.

MRS. H. B. HIGGINS.—A very large Japanese, medium-sized florets; colour very delicate creamy white.

MISS MARY ENDERHAY.—One of the best Japanese incurved, florets medium-sized, grooved and incurving; colour a rich shade of yellow.

EUTERPE.—A short-petalled Japanese, the florets pointed, grooved and rather broad; rosy mauve with a reverse of silvery pink.

MRS. H. BRISQOE.—A Japanese of large size with very long florets; colour bright rosy mauve, silvery reverse.

BEAUTY OF ABELAIDE.—A Japanese with great length of floret; colour dull rosy pink.

MRS. ERNEST CARTER.—A Japanese of fine form, long, closely-arranged drooping florets; colour a pretty, pure shade of deep primrose.

A GROWER.

PURPLE CHRYSANTHEMUMS.

PURPLE Chrysanthemums have been much improved of late years, and many of the old undecided shades have long since been pushed aside for the higher and brighter tones that have been introduced. As crimsons have almost always a golden reverse, so the purples and amaranth coloured varieties have usually a silver reverse—a contrast that is at once effective and pleasing. Some of the best of these are not over large, and therefore are likely to be passed over by the exhibitor. To anyone, however, who desires something striking and useful in the various shades of purple and amaranth there is a very good selection, and among recent novelties may be mentioned Mme. Robert de Massy, a very fine shaped Japanese that bids fair to become a favourite. Congrès de Bourges is another. Souvenir do Mme. F. Rosette and Werther are also good. Deuil de Jules Ferry, although a very telling colour, seems to have passed away already, although only of comparatively recent introduction. Reine d'Angleterre is paler than any of the preceding and not one of the best. Mme. Marius Ricoud is wonderfully bright, and is a pinkish kind of purple when well coloured, as it often is. All the above are seedlings of M. Ernst Calvat's raising.

Some of the Australian novelties are of rather dull shades, Mr. T. Carrington and Australia for instance, but they are very large. Pride of Madford is brighter and richer, and also has the merit of size. Purple Emperor is grand in its deep rich velvety shade, and has only to be seen to be admired. This is also an Australian novelty. Mrs. White-Popham belongs to the paler type. It is very large and likely to be of service as an exhibition flower. The Barrington is an American novelty of the incurved type, but the florets are rather too flat to make it a really pretty flower. J. Bideneope is fairly well known. There are many others in the paler tones of lilac-mauve and pinkish lilac, but these, unless very bright and clear, are apt to become somewhat washed out and lose much of their effectiveness.

C. H. P.

Highly coloured Chrysanthemums.—The note by "A. D." (p. 423) having reference to the richly coloured Lord Cromer recently certificated is to the point. There is, indeed, a lack of such shades as the one named can boast of. At the same time there is more hope of getting good things even of this hue now, as witness the recent novelty, John Pockett, which "A. D." appears to have overlooked. This is also a very fine flower and good in form, scarcely up to the standard of Lord Cromer, and some way behind it in point of colour. The colour in the last-named could scarcely be over-estimated, and anything that will surpass Lord Cromer in this respect will be indeed rich.

Chrysanthemum Mlle. Lacroix.—This, to my mind, is one of the best for cutting; the pearly whiteness and the whorl of the petals make it distinct from all others. As a decorative variety it stands unequalled, there being a freedom in its branching growth, ample, though not exuberant, foliage, and a stalk of sufficient length to suit all purposes. Excessive disbudding of the side shoots and flower-buds, to my mind, spoils it as a decorative or vase flower; with a central and three or four side buds it presents a much more graceful aspect than occurs under severe disbudding. It has long since passed out from the position it once held among show flowers, but I think it will still continue to be largely grown for cutting. While this has been so good this year, Lady Selborne, on the other hand, has been in my case distinctly inferior to what it has been in other years, and the superiority of Mlle. Lacroix is so

marked, that I have almost decided to discard Lady Selborne and increase the numbers of the other. I should not do this but for the fact that there is not much difference in the time of flowering, and the greater substance of the one over that of the other makes it possible for the season of one to extend over the time of both. This is the decision arrived at in my ease. W. S.

CHRYSANTHEMUMS FOR THE BORDER.

THE present season has been favourable for outdoor Chrysanthemums and they have lasted well. Many of the varieties noted are free-flowering Japanese, bright in colour, effective in the open ground, and useful for cutting. At this season of the year some of the London hospitals are not so well supplied by visitors with flowers as they are in the summer, and I know of nothing that gives so much pleasure as a few bunches of Chrysanthemums, which keep for a long time and do not need renewing so frequently as is the case with some other flowers.

MARTINMAS is a very free-flowering, small-sized Japanese, with short, flat florets; colour pale lilac-mauve.

MME. GAMA, a Japanese with long florets of medium width, has a starry shaped flower, somewhat loose in build; also pale lilac-mauve in colour. In

M. LEAQUE FILS, Japanese, with long, narrow velvety chestnut-crimson florets, the blooms are rather large and reverse gold.

MME. AUG. NONIN, a Japanese of medium size, very free, has flat florets. The colour is pale lilac-mauve, centre tipped yellow.

NELLIE BROWN.—A pretty little Japanese with broad, flat florets, golden bronze with golden reverse.

MYCETT WHITE.—A Japanese of medium size, with long narrow florets, twisted at the tips; colour white.

Mlle. MELANIE FARRE.—A Japanese; very full and double, florets narrow; colour pinkish mauve.

M. DELOSSE.—Also a Japanese, with rather stiff flat florets, bronzy red, reverse golden.

CRIMSON PRIDE.—A large and most effective Japanese with rather broad, flat florets; colour deep velvety crimson, golden reverse.

TRIOMPHE DE LYON.—Another most effective Japanese sort; colour bright rosy mauve, with golden tips and centre.

GLADYS ROLT.—A pretty little Japanese, having tubular florets, very narrow and opening at the tips; white.

MME. DE SABATIER.—Japanese, with long, narrow pointed florets; colour bright velvety crimson, reverse gold.

MYCETT BEAUTY.—A very full and double Japanese, free, deep golden orange-yellow.

ROI DES PRECOQUES.—A pretty and effective Japanese with rather slender florets, deep bright reddish crimson.

Mlle. ECLAIRIE MOREL.—Japanese; golden salmon.

IVY STARK.—A delicate little Japanese with narrow florets; colour golden bronze.

M. DUTEL.—A Japanese with flat florets of a delicate shade of deep golden bronze.

AMBROISE THOMAS.—Japanese; a fine crimson.

P. H. C.

NATURALLY-GROWN CHRYSANTHEMUMS.

EVERYONE, I think, must admit the truth of "A. D.'s" statement that naturally-grown Chrysanthemums are less liable to disease than those produced by more artificial means and having large, flabby foliage, the result of much feeding with artificial manures. For many years I grew a number of plants for conservatory decoration and cut flowers, limiting them to pots 9 inches and 10 inches in diameter, the compost mainly consisting of a good sustaining loam, with a sprinkling of bone-meal added, giving the roots no additional assistance until they had well filled the pots, by which time growth was considerably advanced. Farmyard liquid the colour of pale ale was then given at every alternate watering, my aim being to secure a well-ripened growth and blooms not easily affected by damp. I always

found these plants resist mildew better than those fed up for the production of large blooms, the flowers also lasting much longer both on the plants and in a cut state. Moreover, with a view to retarding them as long as possible, I erected a framework over them, covering the roof at night with thick canvas on rollers, the sides being protected with garden mats. So treated they resisted a considerable amount of frost, which would have crippled, if not destroyed, plants having a gross sappy growth. When placed in Peach houses under a canopy of foliage early in October, the blooms often open with a rush and are of a short-lived character. Framework houses with portable glass roofs and strong canvas sides, as suggested by "A. D.," might well be used, not only for the temporary, but also permanent accommodation of Chrysanthemums. Where much cut flower is needed, young plants might be planted out at a fair distance apart and allowed to remain there for say three years. If the growths were thinned out somewhat in spring and the roots top-dressed and assisted with liquid manure, little or no disbudding being done, what a wealth of sprays for cutting might be secured. Years ago, when Chrysanthemums were grown entirely for decoration and cut blooms, gardeners potted on old plants year after year, one central stout stake and a few encircling bands of matting sufficing to keep the growth intact, and what basketfuls of, perhaps small but durable, blooms used to be cut. Plants with a couple of large blooms may look very well crowded together in a group, but from a decorative point of view they are useless individually.

NORWICH.

STAGING CHRYSANTHEMUM BLOOMS.

ANY method of staging Chrysanthemum blooms that is an improvement upon the stereotyped plan must be welcome. Too long we have been accustomed to these hard-and-fast lines of staging the lovely Japanese varieties, which lose so much of their natural grace and beauty when arranged so low and flat on the hard, green-painted stands. Visitors to the exhibition held in the Waverley Market, Edinburgh, for the first time must have felt a keen sense of delight at the charming exhibits of Japanese blooms so numerous and so tastefully arranged in vases accompanied by their own foliage. In many classes other foliage was admitted, which added to the interest and beauty of the exhibits, which were exceedingly numerous. On this occasion no less than 4000 cut blooms were staged—a really magnificent display. Fully three parts of them were arranged in vases or other receptacles, the remainder on the orthodox stand. It was interesting to note the preference of the huge crowd of spectators for the artistic arrangement of the blossoms in vases as compared with those in the orthodox stand. For the past few years the executive of the Scottish Horticultural Association have recognised the unsatisfactory method of staging cut blooms, and set themselves to remedy the evil. Handsome prizes are offered here to the value of £35 for the premier exhibit. Five other prizes in the leading class are also scheduled. Thus exhibitors receive much encouragement to put forth their best efforts. The conditions of the leading class are explicit yet easy, viz.: Twenty varieties, any section, three blooms of each to be staged in vases provided by the society, Chrysanthemum foliage only allowed. Experience proves that the blooms do not last so long in a fresh condition when the foliage growing on the stem bearing the blooms is retained as when stripped; the absorption by the foliage is too great for the freshness of petals. With a view to create a more effective and lasting display, exhibitors are allowed to strip the stems of their natural leaves and tie to them leaves from another plant carrying good foliage. In some instances this is not necessary, as the natural foliage will remain quite fresh the desired length of time. The plants must, however, be quite healthy and the blooms just the proper age for this particular show. Blooms that are not quite developed, or any that are a trifle beyond their date of ex-

pansion, will not carry their own foliage in a satisfactory manner. With a view, too, of placing all exhibitors on an equal basis, the vases provided by the society are of uniform size. Thus uniformity is preserved throughout the show. The blooms are arranged in triplets. Some exhibitors allow 15 inches of stem, others more. All endeavour to arrange their blossoms in such a manner that every one can be clearly seen. If a shorter length of stem than 15 inches is allowed, the blooms have a "squat" appearance; if more than 2 feet is provided, they have a gaunt look, which is increased if the blooms are small. The method of naming the blooms most generally adopted is that of adhesive labels fastened to each vase. A tight plug of Moss is employed to make the stems firm in the vases.

In this class there were six exhibitors, or a total of 360 blooms, providing a rich display. All the exhibits were confined to the Japanese section; exhibitors realise how unsuitable for effect are blooms, no matter how well grown, of the incurved or Chinese section. Varieties with long drooping florets, like Edith Tabor, Simplicity, or Mme. Carnot, and its yellow and primrose sports, lend themselves especially well to this form of arrangement much more so than they do to the orthodox cup, tube, and wood stand.

At the same show no less than eighteen more classes were provided for Chrysanthemums staged in vases, and as fully 1100 specimen blooms, irrespective of the leading class referred to and of classes for decorative and single-flowered varieties, were staged, readers can easily imagine the extent and grandeur of this show.

One of the most interesting classes in the whole show was that for three vases of decorative varieties not disbudded, any foliage to be used. As seventeen competitors took part in this class the effect produced can easily be imagined. The premier exhibit was as near perfection as possible, and well represented the type of Chrysanthemum best suited for room or vase decoration in combination with other foliage. The varieties included in the first prize collection were Source d'Or, Mrs. A. Kirke, a sport from La Triomphante, bronze and golden yellow, a pleasing combination, the remaining variety being yellow Lacroix. With the former were associated deeply bronzed leaves of Spiraea Aruncus; with the yellow variety, leaves of Eulalia zebrina were happily associated. In this class many pleasing combinations were noted, as masses of the pale primrose Elsie, the bright crimson Roi des Precoees, the pure white Lady Selborne and the bronzy tinted Christine.

Single-flowered varieties were encouraged, not in classes for three blooms of each variety, as is so often seen, but huge masses lightly disposed in vases suitable for room decoration. Mary Anderson and its yellow-flowered sport, Annie Holden, were conspicuous in many exhibits, showing the favour in which this type of Chrysanthemum is held. Another method of showing large blooms of Japanese varieties that has much to recommend it is that so well done at Windsor, viz., a stipulated number (twelve) of blooms to be shown in a vase or basket associated with any kind of foliage. In this class the quality of the blooms is a point of importance; the prizes are awarded not merely for arrangement, but for effect combined with the quality of the blooms. Oval-shaped baskets filled with twelve handsome Japanese blooms of exhibition quality, pleasantly associated with their own leaves, foliage of Purple Beech, Scarlet Oak, Ampelopsis, Maiden-hair Fern, Crotons and graceful Palm leaves, with the handle neatly entwined with suitable material, are handsome ornaments in any front hall or drawing-room. Such exhibits are rendered useful in the way that they provide educational lessons for visitors.

E. MOLYNEUX.

The Chrysanthemum rust.—At the Aquarium conference on the new and troublesome disease it was stated by one of the lecturers that the crowded state of the plants and high feeding which obtain to produce large flowers have been the causes of its spread, and that it (the rust) is

never found among outside or border plants. To disprove this I would mention a case which recently came to my notice. A grower of early Chrysanthemums for market, whose land is situated over a mile from any place where Chrysanthemums are cultivated for big or show blooms, and who has not added a new variety to his collection for some four years, has his plants severely attacked by this leaf fungus.—GROWER.

GARDEN FLORA.

PLATE 1200.

BULBOUS IRISES.

(WITH A COLOURED PLATE OF *I. JUNCEA* AND *I. J. NUMIDICA*.)

INCLUDED under this head we have some of the fairest of midwinter flowers, as also many of the most delightful of spring blossoms. In spite of their beauty and grace and the many pleasing and varied shades of colour, we do not find them grown so freely as they deserve. This is perhaps more true of the amateur than the professional gardener. Hence it is that certain sections of the flower and the so-called Spanish or Niphium Iris more than all else find the greatest favour, and are therefore grown in immense quantities for cutting. And it is just this section of the genus that would appear best fitted for cultivation in British gardens, always, however, doing best where the soil is comparatively light, sandy, and, above all, well

Iris persica.

drained. Of some groups of hardy bulbous plants the season of flowering may be very considerably extended by delaying the season of planting. Such a system, however, cannot be adopted in the case of these bulbous Irises. It is true of them that they enjoy a resting period, but it is needful also to restrict such a rest to certain limits. Indeed, so far as the amateur is concerned, there is no safer method to be followed where lifting such things has become a necessity than to lift them and dry, clean, sort and replant again within a month or six weeks. During the period of rest the best possible position for the bulbs is any open place where a free current of air may be secured to them, and not, as is too often the case in small gardens or with many amateurs, to convey them to the potting shed or greenhouse and allow them to remain in boxes or

* DRAWN FOR THE GARDEN in Messrs. Wallace's nursery at Colchester by H. G. Moon. Lithographed and printed by J. L. Goffart.

baskets in bulk as lifted. This is an error, the evil of which cannot too strongly be emphasised, and one that most frequently ends in failure another year. A capital way of giving all bulbs

The only way of at all extending the flowering season of both sections is to plant in various positions. This will give a useful variation in the time of flowering, and if the latter can only

English Iris.

the rest they need is to spread them out on boards or on a hard gravel path and place a spare light over them. A large pot at each corner will raise the light and throw off wet, and a sack or two will keep them shaded from hot sun. With respect to these, however, the drying and resting are most needed for the English and Spanish kinds, and only then in certain cases where soil or situation is calculated to injure if the plants were allowed to remain. In not a few gardens, too, these things become patently and subject to disease. A species of dry rot attacks the corms to the very core, while retaining a comparatively sound exterior. This attacks them when, by accident or design, the plants are out of the soil longer than they should be. Not a few who have attempted the retarding process on the lines of keeping the bulbs too long in the dry state have proved this to their cost. It is also curious that the flowering of these plants is not deferred at all in proportion to the time between any two plantings. This is so when a

be extended by days rather than weeks, it is worth attempting where quantities of cut flowers must be had. It should be noted, however, that a fairly long season of flowering results naturally, the Spanish group flowering first, the English Iris forming a quick succession. The season for planting such things is already with us, and the early-planted ones have made abundant root since the late rains. All the same, it is by no means too late for planting this year, but it is important the work should be carried out at once, and equally important that good sound bulbs be secured. From 3 inches to 6 inches deep will be ample for all the kinds, the former depth being best for such as *I. reticulata*, and the latter for the taller forms of *Niphium* and *xiphoides*.

The following species are worthy of careful cultivation, flowering as they do in winter and quite early in the year. *Iris Bakeriana* is one of the most beautiful of the whole race. The charming *I. Histrio* is very early, and has porcelain-blue flowers delightfully spotted; the allied *I. histrioides* has larger and more handsome flowers that are even earlier. The beautifully marked *I. persica* is perhaps the dwarfest of all. Of the several forms of the netted Iris, *I. reticulata*, the type is perhaps the finest garden plant. Other charming things are *I. Vartani* and *I. Vogehiana*. This may be described as an early *I. persica*, which it resembles in growth. It is a variable species, generally shades of silver-grey predominating, and having spots of rose and purple. All these are specially suited to pot culture or the rock garden, where on warm, sunny ledges above a thin carpet of greenery they would form a most delightful series quite early in the year. If grown in pots it should not be with any notion of so-called forcing, as nothing more certainly destroys the very charm that pervades every one, viz., their exquisitely delicate and varying shades of blue, sky-blue, and those pleasing silver-grey tones that almost everyone admires. In another little batch may be placed the more leafy kinds, of which *I. caucasica* and *I. orchoides* are representatives. The latter bears a profusion of rich golden-yellow flowers spotted with black, certainly one of the most satisfactory of this type, and at the same time the most vigorous in point of growth, the plants readily attaining a foot or 15 inches in height. The exquisite *I. sindjarensis* resembles *I. orchoides*, but has flowers of a pearly blue shade produced at intervals on the stem. No mention has been made of the midwinter kind, *I. alata*, also called *scorpioides*, but which, owing to its flowering in January, should be grown with protection.

Not the least of this important race are the two representatives of the Rush-leaved Iris, *I. juncea* and *I. j. nudaica*, the former having flowers almost golden, while the latter is

characterised by flowers of a pleasing and delicate pale primrose, a shade so soft and beautiful, that it at once found many admirers when the plant was exhibited in June last by the Messrs. Wallace before the Royal Horticultural Society at the Drill Hall, when the variety secured the award of merit. Both kinds are faithfully depicted in the coloured plate in to-day's issue, and for early summer flowering are among the most valuable of the whole family. As an effective bed or group, *I. juncea* would be difficult to surpass, the rich tone of yellow displaying itself to advantage at a distance of 100 yards or more, the pale primrose form pleasing all by its delicate grace and beauty. E. J.

THE WEEK'S WORK.

FRUIT HOUSES.

STRAWBERRIES IN POTS.—The first batch of these for extra early forcing should now be selected and placed in a light, airy house. For the first week or so it is not advisable to water much or at all, so long as the plants do not suffer. When somewhat dry at the roots it is advisable to go over them and press the soil down firmly, look to the drainage, weed if required, and wash the pots, but do not remove other than the dead leaves. These first early plants should, if possible, be stood upon shelves near the glass. A vinery or a Peach house just about to be started will suit them after this attention has been given.

Spanish Iris.

A properly-arranged Strawberry house is, of course, better as time progresses. My first lot of plants has to-day (December 3) been taken under glass. These will for a few days remain as above suggested, and then be stood upon shelves in the Strawberry house. The choice for this purpose has fallen upon *La Grosse Sucrée* again. These for the early batch are all in 4 1/2 inch pots as an experiment, owing to the plants in 6 inch pots last spring not drying up so freely as I should have liked them to. Another lot will follow in ten days' time, but these will be in 6-inch pots. So far, owing to pressure of work, I

Iris reticulata.

period of several weeks separates the planting of the bulbs. The chief difference would appear to be represented by stature and a loss of growth and general vigour than aught else.

have not housed any of the stock, *i.e.*, placed them under glass in cold frames. So long as no serious frost sets in they will be safe and better, too, than if packed together closely in frames, even if the lights be off when not frosty. If the present open state of the weather continues for a few days longer my stock of St. Joseph, which yielded fruit up to November 12 under glass, will be planted out on a west border which is in readiness for them, the object being to prepare them for, first, yielding early runners to pot up in July, and next to bear an autumnal crop, the early trusses being picked off when they first appear.

PEACHES AND NECTARINES.—For the first early forcing of these fruits I depend entirely upon pot trees, finding it to be more convenient and economical. The first selection of these was made on December 2, the trees having since the end of October stood in a cool, well-ventilated house. Nectarines are given the preference thus early over Peaches, being found more reliable on the whole. Cardinal is the one variety selected, with a few trees of Amsden June, Stirling Castle, and Early Grosse Mignonne Peaches. The second variety, although not a first early Peach, flowers at the same time as the first earlies, being very prolific in pollen; hence its choice. In addition also I have found that it is not a bud-dropper. These trees do not fill up the early house, a light span-roof structure, but it will be filled later on with Waterloo, Alexander, and Hale's Early. These varieties are at present out of doors, where they will remain until it is seen that the flower-buds are just showing colour. Then they will go inside at once, this precaution being taken to guard as far as possible against their proclivity for bud-dropping.

FIRST EARLY PLANTED OUT TREES.—The middle of December is, on the whole, quite soon enough to start these. If started at the beginning of the month a week may be gained, it is true, but unless the trees be thoroughly established and reliable by previous tests, the gain is not commensurate with the risk. I have a "one-tree" house that is annually started at the same time as the first lot of pot trees, but it is the outcome of years, the tree now being, as it were, acclimatised to the procedure and reliable. For the first three weeks no fire-heat will be given unless there is a risk of the inside temperature falling below 37°. The trees will be syringed once or twice daily, and the houses kept fairly close with no fire-heat. This applies to both pot and planted-out trees, no variation in treatment being recognised.

LATER HOUSES.—Proceed with the routine work of the season and endeavour to be well advanced with it all by the end of this month. With respect to the pruning, which should be the first operation, previous experience with the same trees will indicate the course to pursue. In some soils, as in varieties, it is safe to train the shoots thinly. In others it is not a good course to pursue, for others no doubt, as well as myself, have noted the tendency to set the crops upon the medium and small wood. If this be so, it is plain that this wood must be retained, especially short spur-like shoots, for which I have a personal liking, regarding them safe for one fruit each. On the other hand, it does not do to cut away the strong, well-placed shoots, but the vigour of such, another season, must be reduced by not disbud-ding too early or too freely. What will suit in one case will not in another, as I have noted in many instances. One case in particular occurs at the moment in which the trees were the perfection of shape, with every branch, so to speak, in its place, but the crop was a failure. True, if the few extra fine fruits were staged in competition they would be almost sure to win, and credit would redound as a matter of course. This, however, is not satisfactory cultivation. A full crop should be the aim, and nothing short of it on the average. These trees in due time, by their vigour, brought about by early disbud-ding and light crops, became a prey to canker and are now trees of the past. There is not a gardener, perhaps,

who has not noted that a Peach tree when it shows signs of old age bears its finest fruits. What is this caused by but by a check in the flow of the sap, through, perhaps, a contraction at the contact of stock and scion or by remote symptoms of decay? If the trees be now at all over-luxuriant, guard against still further exciting them by manure of any kind until a good set of fruit has been secured, then possibly a phosphatic manure will assist them. When it is decided to close a house for forcing, call into use at once the XL All vaporiser as a safeguard against greenfly, and again before the earliest flowers open. In neither case is a strong dose needed when thus taken in time. Do not omit the all-important matter of watering the borders if inside ones; a dry border may cause bud-dropping in any case. Avoid, if possible, the introduction of an excessive number of plants into the house, this of itself often being the cause of an attack of greenfly. Too many plants of a tender character in these houses often mean that they are kept too close for the real occupants of the house.

CHERRY HOUSES.—The culture of Cherries of the best dessert kinds ought to receive more attention than it does under glass. In order to be on the most certain road to success, it is advisable not to grow the Cherry in a mixed house unless it be an absolutely cool one, in which case there will probably be ventilation sufficient to meet the case. I never close the Cherry house, even with a few degrees of frost outside, until the fruit is set and nearly or quite safe over the stoning period, yet it is ripe by the third week of April. Guard, therefore, if commencing the culture of Cherries under glass, against exciting the trees too much. Do not close the house absolutely, but with a free circulation have a little warmth in the pipes. If dealing with trees planted out, keep such now entirely cool, as the least amount of warmth will start them. Let them have a thorough cleansing if need be. If any great amount of pruning has to be done to trees growing in borders, dress the wounds with styptic in the possible event of gumming. If in past years the fruit has dropped during stoning, it may be taken that phosphates are deficient, and manure accordingly as quickly now as possible.

HORTUS.

KITCHEN GARDEN.

NECESSARY WORK.—With a change in the weather much of the work hinted at in previous calendars will now have to be done. The first to claim attention will be the protection of vegetables. The Bean crop, both runner and dwarf kinds, should not be left any longer. Stakes needed for future use should be stored. Now is a good time to get in the supply of stakes for another season, as these may be prepared before other work of more importance needs attention. The leaves on fruit trees have been longer than usual in falling. This will not be advantageous, as till these are cleared the quarters cannot be dug or cleaned up for future vegetable crops. I am busy draining the walks where necessary, and after this is done, it will repay to add a light covering of new gravel to give the walks a bright appearance. Every opportunity should be taken in frosty weather to cart manures and soil on to the surface. Many old garden soils would be much improved if old potting soil, Cucumber, Vine, Melon beds or other material could be added. These are more valuable than heavy coatings of animal manure yearly. Broccoli plants, as soon as the heads are cut, should be cleared and the land prepared for future crops. The Autumn Protecting variety is later than usual this year owing to late planting, so that I fear the heads will be small. The plants should be gone over two or three times a week, and plants with heads fit for use should be lifted and placed under cover. The late varieties of Broccoli will now have made their growth, and protecting, as previously advised, by heeling over should not be delayed. Mint and Tarragon should be lifted for forcing. These grow freely

in an early fruit house placed near the glass. Seakale will now force more readily, and if roots are lifted, trimmed, and laid in the soil they will be ready for use in severe weather, as it is an easy matter to cover with long litter. I place the roots in warmth every fortnight from this date, and as it may be wanted in larger quantities at the Christmas season, this should be borne in mind. I find the roots do not force so readily this year, owing to their late growth. Asparagus will need more time than Seakale, unless there is genial warmth under the roots. If on manure or leaves, growth will be general in three weeks with a top temperature of 60°. To maintain a regular supply I put in enough roots every three weeks up to the end of January, after that date relying on the forced beds in the open. Time will be saved by lifting the bulk of Jerusalem Artichokes and pitting ready for use, sorting out those required for seed. The land may then be prepared for future crops, and wherever change of quarters can be given the return will be better. Globe Artichokes should be protected in gardens where loss of plants occurs. Turnips for use in mid-winter should be lifted and treated as advised for Potatoes: the quality will be better if in a clamp, and in storing, the large roots should be used, as these keep badly under any conditions. Small bulbs are best left in the ground, and these will benefit by having soil drawn up to the leaves; the yellow-fleshed varieties will not need this protection. The hoe should be kept going between young crops, such as spring Cabbage and other small roots, whenever the soil is dry.

CARROTS.—These up to this date are in their growing quarters, and though it is usually advised to lift them in light, well-drained soils, there is no need to do so. The land must be free of wireworm, as this pest makes sad havoc of the roots. The flavour of Carrots left in their growing quarters is superior to that of roots lifted and stored. The roots are not injured by frost, and they may be kept much longer in the spring if lifted just as they commence to make new growth and placed in moist soil under a north wall. The late summer-sown Carrots for spring use are now growing freely, and if these small Carrots go through a hard winter, the larger ones will certainly do so. The last sowing will be benefited by a dressing of soot. Late-sown Carrots are a great boon to growers who need this vegetable in quantity in the early spring, as, no matter how well frame Carrots are grown, they are none too early or too plentiful. These will be little inferior in quality and may be had in quantity. Carrots in peaty or light soils grow freely in mild winters if well treated.

LEeks.—The earliest Leeks will now be valuable as a winter vegetable, and the quality will be improved after the heavy rainfall. The most useful Leeks are the medium-sized ones, not too long, so that the blanched portion may be served on toast and the green part will be useful for flavouring. Later lots will now benefit by having a little earth added to the rows, but in doing this the weather should be studied, and if too wet or frosty delay will do no harm, as the green portion of the plant is very hardy. Plants for latest supplies, owing to the summer heat and late drought, are smaller than usual, but growth is still active. I have given liquid manure freely, and dressings of soot will benefit the plants if applied in rainy weather. Now is a good time to sow in boxes when large roots are needed for early autumn or for exhibition. I prefer to sow in a cold frame. The frame may be removed in the early spring, and the plants will be strong for April or May planting.

ONIONS.—The autumn crop should now be in their winter store. It frequently happens that the crop is placed in bulk till an opportunity offers to sort the bulbs and rope or tie in bunches. Either of the latter should now be done, as if left too long few vegetables suffer sooner, the outer skin decays and the bulbs go soft, growing out and being of no use for keeping. I find Onions keep well suspended from the roof with a free circulation of air. Those who grow large Onions

will need to sow under glass as soon as possible; indeed, many sow in November or earlier, but good specimens may be obtained by early December sowings. The best system when only a small quantity is needed is to sow in boxes, as these are more readily moved about as growth increases. The autumn or August-sown seedlings this year are none too plentiful. I made two sowings, but owing to the drought much of the seed failed to germinate, so that it may be advisable to sow under glass to get a full crop. The hoe should be used freely between the rows of plants in favourable weather, and dressings of soot or wood ashes will be beneficial.

ENDIVE.—The autumn rains have made the Endives grow freely, and with the growth so tender it will be well to protect earlier plants that are blanched, as these suffer sooner than the greener leaves. I am housing in frames the larger plants, lifting with a ball of earth and removing any decayed or useless leaves. I find the plants from this date will blanch much better in a dark place, such as a Mushroom house, than covered in the frames, as in these they damp badly. In very severe weather the plants for spring supply will well repay for a little protection in the way of dry Bracken or long litter. There is no difficulty in having a good supply during the next two months, as these plants will have finished their growth. Some of the medium-sized plants should be lifted for a succession, and if placed in a cool fruit case or unheated house they will continue growing if not crowded and given a free circulation of air. The Large-leaved Batavian is the best keeper.

LETTUCE AND OTHER SALADS.—Lettuce will have been more plentiful than usual owing to the mild autumn, but from this date it will be well to lift and house any plants large enough for present use. The Cos varieties, such as the Brown and Black-seeded, will winter in the open on warm borders if the plants are not too large, and any above half-grown it will be well to protect. Much the same remarks apply to Lettuce when given glass protection as advised for Endive. Chicory will be a welcome addition to the salads. If a few roots are placed in a dark, warm place every fortnight, the new growths will be ready in ten days. Dandelion and sprigs of Tarragon should be forced like Chicory, but the Tarragon will need more light. This does well in a frame. Those who have a deficiency of Lettuce should sow seed thinly in boxes in a warm place, and when the seedlings are 3 inches high or so cut them over like Mustard and Cress. Mustard and Cress should now be sown fortnightly. S. M.

Stimulating manures.—There is a great tendency now-a-days to employ in plant culture highly concentrated manures of different kinds, which are so exciting that their effect upon the plant is seen very shortly after the application. The use of such manures is perhaps justified where the sole object is to bring the plant to the highest possible pitch, but woe-betide the cultivator who attempts to grow it on after being fed up with one of the many highly stimulating manures, as, though the shoots may be thick and sappy and the foliage richly coloured, the constitution of the plant is so weakened that in most cases it will merely exist. Again, plants that have been fed up in this manner are quite useless to propagate from, as cuttings even of subjects with which there is no trouble when in a normal state will refuse to root when taken from these plants. The Chrysanthemums that are grown for the production of huge blooms supply a case in point, and so do the Pelargoniums brought into Covent Garden Market during the season. In the neighbourhood of London, too, these fed-up plants fall a far more ready prey to that bane of cultivators—fogs—than those grown under normal conditions. Where the permanent health of the plants has to be considered, stimulants, if needed, should consist of manure-water made from the manure of cows or sheep and well diluted.—H. P.

AN AUGUST VISIT TO TRESKO ABBEY GARDENS.

During a short summer cruise along the south-western coast I was afforded a welcome opportunity of renewing my acquaintance with the Isles of Scilly. Passing the bold rock mass of Peninnis Head in the gloaming, the yacht anchored in St. Mary's roads as night was closing in, and had scarcely tautened her cable ere torrential rain commenced to fall, which continued at intervals throughout the night. The following morning broke cloudlessly fine, and in the early hours a shift of anchorage was made, under local pilotage, to the picturesque New Grimsby harbour, where on the one side the high land of Treseo slopes down to a sandy beach, and on the other, Bryher rises abruptly from the shore. On the seaward side the rugged Hangman's Rock juts out into the channel, which, near the entrance, is flanked by the sturdy ruin known as Cromwell's Tower rising from the water's margin, while across the flats and the lately-quitted roadstead lies St. Mary's, with the roofs of Hugh Town gleaming in the sun.

It was a little late to see the abbey gardens at the zenith of their summer glory, for the long spell of dry weather had unduly curtailed the flowering season of the Kalosanthus (*Crassula*) and of the earlier-blooming *Mesembryanthemums*, which three weeks before must have presented a vision of unparalleled brilliancy. Here and there, however, a dozen or so bright flower-heads of the Kalosanthus, which grow in huge masses among the rocks, gave evidence of the quality of their July display, while many of the *Mesembryanthemums* were still marvels of gorgeous colouring. Especially was this the case in a newly-excavated rock garden, where, associated with scented-leaved *Pelargoniums*, flesh-coloured, pink, rose, and crimson, Lemoine's *Glaholi*, and *Montbretias*, their vivid tints glowed in the morning sunshine. The Treseo Abbey gardens contain the largest open-air collection of *Mesembryanthemums* in the British Isles, 120 varieties being under cultivation, many being of exceptional value on account of their brightly hued flowers, while others are interesting by reason of their distinct foliage, *M. tigrinum* being especially curious in the latter respect, the spiny, ceneave leaves, half unclosed, bearing sufficient resemblance to the tiger's open fanged mouth to account for its name. Among the ruins of the old abbey the African Lilies (*Agapanthus umbellatus*), blue, lavender and white, made a delightful picture, while a long wall, 6 feet high, was salmon-pink with the blossoms of the Ivy-leaved *Pelargonium Mme. Crousse*. *Crinum Moorei* was in bloom, and the lovely *Sparaxis pulcherrima* was bearing its graceful arching flower-wands, 5 feet and more in height, the rose-pink drooping bells, poised from delicate thread-like footstalks, the deep blue *Commelina coelestis* blossoming profusely hard by. The heavy rain of the preceding night—the rain gauge measuring a fall of close upon 1 inch—had freshened the foliage and moistened the ground, little pools in places evidencing the volume of the downpour. The abbey itself is built upon the solid rock, which slopes downwards from its foundations to a lower level and affords ample scope for rock gardening on a large scale. A dip in the rock has lately been fashioned into a series of pools, one above the other, in which Water Lilies are now growing, many handsome varieties being represented, among which may be mentioned *Nymphaea flava*, *N. Martiacea sulphurea* and *N. M. s. grandiflora*, *N. M. Chromatella*, *N. M. carnea* and *N. Laydekeri rosea*, while the lowest rock pool is set aside for the sole benefit of the Cape Pondweed (*Aponogeton distachyon*). The Maiden's Wreath (*Francoa ramosa*) grows freely in the open at Treseo, and *Fuchsia fulgens* may also be seen in flower. *Muschia Wollastoni* had produced a spike between 3 feet and 4 feet in length of greenish yellow flowers, unique, if not particularly effective in appearance. *Hedychium Gardnerianum* was in bloom, as were Lilies of the auratum, speciosum and tigrinum sections, as well as Cannas and *Tritonias*, while *Portu-*

lucas showed their bright hues of scarlet, rose, orange and pink. *Kniphofias* bore their vivid spears of bloom and, by a little watercourse, the *Araums* were growing in a thicket, while *Hydrangea* bushes were blossoming on all sides. What must be a striking sight at another season of the year was a large bed of Guernsey Lilies of different varieties, which are said to thrive wonderfully under their treatment, one item of which is surfacing the bed with sea sand every year. Against a wall *Mandevilla suaveolens* was bearing its large white scented blossoms in profusion, while the yellow *Abutilon* and *Swainsonia alba* were also in flower. Against the same wall were growing a large double Pomegranate, *Tecoma radicans* and *Leonotis Leonurus* 7 feet high, which had flowered well through the summer. One of the borders in this garden is edged with a wide margin of *Lithospermum prostratum*, which in the spring is a mass of deep blue. Close by a large clump of *Iris stylosa alba* is growing, and in another portion of the garden *Iris Robinsoniana*, with leaves 6 feet and 7 feet in length, is seemingly in vigorous health and is said to flower well. Of

FLOWERING SHRUBS AND TREES

the following were in bloom: *Anopterus glandulosa*, with its panicles of flesh-white flowers, *Banksia grandis*, *B. littoralis* and *B. serratifolia*, the Allspice Tree (*Calycanthus grandiflorus*), the golden-flowered *Cassia corymbosa*, *Clethra arborea*, 12 feet and more in height, thickly studded with its sprays of white-flowered racemes; *Desfontainia spinosa*, with its scarlet tubed flowers; *Eriostemon buxifolius*, *Escallonia organensis*, *Heliocarpus cuneatus*, *Melaleuca hypericifolia*, with its cylindrical scarlet flower-spikes; *Olea fragrans* and *Polygala*; while amongst those out of bloom were *Abutilon vitifolium*, both the lavender and white forms; *Acacias* in variety, of which *A. dealbata* looked particularly healthy; *Boronia*, *Braehyglottis repanda*, *Cantua dependens*, *Callistemon speciosus*, *Correa* in variety, very vigorous in appearance; *Dodonia excelsa*, which was bearing its winged seed-vessels; the Camphor Tree (*Dryobalanops aromatica*), *Echium calythisum*, 8 feet through; *Edwardsia microphylla*, *Embothrium coccineum*, *Eurya latifolia*, which flowered this year; *Griselinia lucida*, *Illicium religiosum*, bearing curious seed-vessels in place of its beautiful white flowers; *Libonia floribunda*, several trees of *Metrosideros robusta*, which in July had been masses of crimson bloom-clusters, and *M. floribunda*. In the former variety there were many cases in which aerial roots had been formed on the branches. Myrtles were in superb health, and an Orange Tree was growing in the open, while there was a fine specimen of *Myoporum laetum*, whose lance-shaped leaves were covered with numerous pale-coloured spots, which proved transparent when held to the light. *Pimelea decussata*, *Isoralia pinnata*, and a fine specimen of the double *Sparmannia africana* were also growing in the gardens, where the Himalayan *Rhododendrons* were evidently in the best of health and are gradually ousting the less decorative *R. ponticum*. Amongst other trees were a very vigorous specimen of *Araucaria Bidwelli*, a specimen of the Norfolk Island Pine (*A. excelsa*) 20 feet in height, and close to the abbey a large tree of *Casuarina quadrivalvis*.

Several varieties of Bamboos are grown, amongst which are *Arundinaria Simoni*, *A. falcata*, *Phyllostachys aurea*, *P. viridi-glaucescens*, *Thamnochloa Falconeri*, and others. Of Palms there is a fine specimen of *Chameroops Fortunei* 15 feet in height, while *C. excelsa*, by some thought synonymous with the former, but here exhibiting certain divergence, is of equal stature, other Palms grown comprising *C. humilis*, *Scaforthia elegans*, *Corypha australis*, and *Phoenix canariensis*. An exceedingly fine specimen of *Seafortia elegans* was, unfortunately, lost during the winter of 1893-94.

Puya chilensis was bearing a tall autumnal flower-spike, after having perfected one 15 feet

in height during the preceding spring, when *Doryanthes excelsa* produced a flower-spike over 10 feet high. *Foureroya longava* grows rampantly in the gardens and often throws up lofty flower-spikes, one of these having attained a stature of 25 feet. *Beschornerias* also flower freely, while *Dasyllirion acrotichum* and *Rhodostachys littoralis* grow on the sunny rocks. Many species of the *Aloe* are grown. *A. ferox* had already bloomed, and *A. spicata* was throwing up its flower-stems. Between forty and fifty varieties of *Agaves* are cultivated, the pockets and crevices of the sloping rock evidently suiting their needs to perfection. Fine specimens of *A. americana*, long ranks of which are often to be seen in flower, are common, while other varieties grown embrace *A. applanata*, *A. coccinea*, *A. concinna*, *A. Celsiana*, *A. ferox*, *A. rubro-spinosa*, and *A. Verschaffelti*. The New Zealand *Flax* grows like a weed on the island, and clumps of various kinds are to be found in the gardens, among these being the type, *Phormium tenax*, *P. t. variegatum*, *P. atropurpureum*, *P. Colensoi*, and *P. Guilfoylei*. The large specimens of *Dracæna australis*, which form the far-famed *Dracæna* avenue, a charming illustration of which appeared on p. 197, vol. xlviii. of *THE GARDEN*, are in some cases, unfortunately, showing signs of decreasing vigour. After reaching a certain size the tap-root appears to encounter some substance inimical to the health of the tree, which gradually loses strength and commences to die back from its extremities. The hybrid *Dracænas*, of which large numbers are raised from seed, do not, I was informed, push down a tap-root, but throw out their roots laterally, and should not, therefore, be subject to the loss of vitality apparent in the older specimens of *D. australis*. *Dracæna Draco* (the Dragon Tree) is also grown at Tresco, and I renewed my acquaintance with the fine *Cordyline indivisa*, which I first saw in the spring of 1895, and which was subsequently figured on p. 86, vol. xlix. of this paper. It was at that time bearing a huge bloom-spike, but during the past two years has not been allowed to flower, as the plant was apparently weakened by the strain of flower and seed-bearing. The broad sword leaves, fully 4 inches in width, are very different from those of *Dracæna indivisa* with which it has been confounded. *Gunnera scabra* and *G. manicata* are both grown, the former, although planted in a damper situation, being far surpassed by the latter in size of leaves. Many plants possessing scented foliage are cultivated, the list comprising amongst many others *Laurus aromatica*, *L. camphora*, and *Geranium tomentosum*.

Rare and remarkable as are many of the occupants of the Tresco Abbey gardens, it is, perhaps, in the sheltered grove, where the great

TREE FERNS

spread their giant fronds, that the breath of other climes most powerfully pervades the consciousness: climes with which the rheas, stalking sedately over the close sward hard by, and the strange waterfowl, that break into ripples the placid surface of the pond, seem more in keeping than with the atmosphere of northern skies. In this sanctuary the mid-August sunbeams flicker fitfully amongst the foliage, where the hammocks swing beneath the trees, filtering through the delicate tracery of the Fern fronds, here and there touching their brown trunks with shifting lights and dappling the broad leaves of the *Musa* with spots of lighter green. Here the Tree Ferns, most of which have been raised from seed, are evidently at home. A fine *Cyathea medullaris*, put out from a pot four years ago, has now fronds 7 feet in length, while *Cyathea dealbata* is also well represented. *Dicksonia antarctica* and *D. squarrosa* have both attained a height of about 15 feet and carry fine heads of wide-spreading fronds, one large specimen of *D. antarctica* with a triple stem having been planted in the late Mr. Augustus Smith's time. In the equable climate of the Isles of Scilly it is unusual for any permanent injury to be done to the Tree Ferns during the winter, but a large *Cyathea* was un-

fortunately killed by a sharp frost succeeding a period of mild weather in 1894. Other Ferns are well grown within the boundaries of the Tree Fern grove, *Lomaria proceræ* being remarkable for its vigour.

Among the Tree Ferns an air of peace reigns supreme, but, should one wander but a few yards further, a vision in which peace has no part is conjured up, for here is Valhalla, where, in an open verandah, rest the tempest-riven figure-heads of many a fine ship wrecked in the fierce winter gales on the outlying reefs that like a network encompass the Western Isles.

S. W. F.

FERNS.

OUR BRITISH FERNS.

At the present time these are not so popular as they deserve to be, yet, glancing through the long lists of varieties enumerated, and from the

sirable Fern, and the numerous beautiful varieties are certainly not excelled by the choicest of our exotic Ferns. I think that one reason for these beautiful hardy Ferns not being grown so extensively as they deserve is that those who have planted them have not paid sufficient attention to the conditions they are found under when growing naturally. In my rambles in the country I have seen the most beautiful specimens, but always growing in sheltered nooks and where the crowns get covered with fallen leaves in autumn. Some of the finest specimens I have seen have been growing in deep hollows sheltered on either side by hedges, and it is only when so protected that they are seen at their best. When growing them in pots, it should be remembered that they are more liable to damage from frost than when in the ground, and also that they do not get the natural protection afforded by leaves, which, as they decay, form a good surface dressing for

Polystichum angulare Kitson.

number of first-class certificates that have been awarded for varieties, it is evident that in the past they must have been even more popular than the exotics are at the present time.

Of *Aspidium* (*Polystichum*) *angulare*, I find there are nearly 150 varieties enumerated in the list of Ferns cultivated at the Royal Gardens, Kew, and this list does not include many of those which have received first-class certificates from the Royal Horticultural Society. (There are upwards of forty which have gained this distinction.) The ordinary type is a most de-

the new roots in the spring. When grown in pots all the *Polystichums* should be potted in good fibrous loam and leaf-mould, and although considered quite hardy, the protection afforded by covering them with some straw or Bracken will be beneficial, and they may be started into growth early in the year by placing them in a little warmth. In early spring a little artificial heat will assist in the development of the new fronds, but during the autumn this will only induce premature growth and will weaken the crowns.

All the hardy Ferns require a period of rest, and if this is not given at the proper time they will be weakened, and instead of the fronds increasing in size they will get smaller. During the resting period they should not be allowed to become too dry, the chief thing being to keep them in a cool, shady position and avoid all stimulating manures. Of the varieties, the one here illustrated (*Aspidium angulare* var. *Kitsonae*) is one of the most desirable, making a bold plant with broad, sturdy fronds. Of the choicer sorts, those of the *plumosum* type are the finest. There are also several fine forms of the *proliferum* type. Wollaston's variety, which I believe was found growing wild, is a fine form. In a recent note I referred to the propagation of these from the bulbils, but when left undisturbed in a genial position young fronds will be produced from the bulbils, forming a dense mossy growth along the main stem. There are also many beautifully crested varieties of *A. angulare*, and these may be raised from spores. By carefully selecting the best-developed fronds for spores further improvements may be made. Raising seedlings and watching their development are most interesting, and some good things will generally occur in a batch of seedlings.

A. HEMSLEY.

POLYPODIUMS.

This is the most extensive genus we have in Ferns, and includes widely distinct species. One can hardly conceive why such widely distinct Ferns should be included in one family. Taking those with the spreading rhizomes which belong to the section with fronds which, when matured, drop off and leave only a scar on the rhizome, of which *P. vulgare* (our native Polypod) is a good example, and then take the *Phegopteris*s, which have their fronds continuous with the stem or rhizome and do not fall off. In Nicholson's "Dictionary of Gardening" it is stated that there are upwards of 450 species, and add to this the number of garden varieties, the list would be a very long one. It is rather remarkable that in such an extensive genus there are so few found useful for general culture. Those of the *Phlebodium* section are the most conspicuous. *P. aureum*, which is so largely grown for market, is a beautiful Fern, making a well furnished plant in a 5-inch pot or a grand specimen for an 8-inch or 10-inch pot, and may be raised by thousands from spores which, if collected at the right stage, rarely fail to germinate. The variety *glaucum*, which is of more slender growth and has a more distinct bluish tint to the fronds, though not so extensively grown, is a very desirable Fern. To this another very distinct variety has lately been added. I refer to *P. Mayi*, which has the beautiful glaucous tint, the pinnae deeply corrugated and fringed on the margin. Should this come true from spores, it will prove a most valuable addition to our market Ferns. *P. sporocarpium* is another variety of this section, similar in texture to *glaucum*, but the fronds stand quite erect instead of drooping, and the rhizomes are not so thickly covered with scales. *P. nigrescens* is a distinct and useful species with irregularly divided fronds. A curious characteristic of this species is that the spore cases are sunk, and the upper surface of the fronds shows a regular row of knots or protuberances on either side of the midrib. A curiously crested form of this was lately exhibited and received an award of merit from the Royal Horticultural Society. It was said to be of hybrid origin between the above and *P. vulgare grandiceps*, but I should say if a hybrid at all, it has more affinity to *P. phymatodes cristatum* than *P. vulgare*.

Of those with long pinnate fronds, *P. subauriculatum* is the most effective. Grown in the stove under favourable conditions it will make very long fronds, and it is only when suspended that it can be grown to perfection. It is perhaps

better known as *Goniophlebium*. Another of this section is *appendiculatum*; the fronds are not so long and more resemble those of our native *P. vulgare*, but have a deep bronzy, almost crimson tint. It requires some care to succeed well with this; the roots do not go deep, and if grown in shallow pans, in a rough compost consisting of peat, fibrous loam, sand and broken crocks, with good drainage, it will succeed better than when given more depth of soil. This applies to most of those with slender, spreading rhizomes. *P. pectinatum* and *P. plumosum* may both be raised from spores and make better plants than from division. In *P. diversifolium* the fertile fronds are pinnate with long, narrow pinnae. It also forms some short, broad shell-like fronds. *P. rigidulum* has the same characteristics, with longer fronds; this is a grand Fern for wall pockets. In *P. quercifolium* the barren fronds closely resemble an Oak leaf, but the fertile fronds grow nearly erect, and are of a stiff, rigid texture, closely resembling *P. Heracleum*, which has broad, pinnatifid, sessile fronds of a thick, rigid texture. It is curious how closely this resembles *Acrostichum drynarioides* except in the fertile fronds. In the latter the terminal segments or pinnae are very narrow and the sori continuous, while in *P. Heracleum* the sori are dotted over the under surface of the broad pinnae. *P. Meyenianum*, of which a good cut occurs in Schneider's "Book of Choice Ferns," is known as the Bear's-paw Fern, owing to the thick scaly rhizome closely resembling a bear's foot. In this the sori are produced on the terminal pinnae, which are much contracted. It is one of the most beautiful of the genus when well grown. This should be grown in baskets or shallow pots, and when in pots the crown should be kept well above, so that the rhizomes can spread over the rim of the pan or pot.

Another distinct section of the Polypodioids is that with simple or undivided fronds. *P. irioides*, *P. muscifolium*, *P. phyllitides*, and *P. crassifolium* are good examples; these, though not generally cultivated, make fine decorative plants, especially when raised from spores. They require a stove temperature and delight in a shady position, though the fronds are of a thick leathery substance. I find they do not stand exposure so well as many of less substance. *P. crassifolium* and *P. phyllitides* are, perhaps, the most serviceable, and, being totally distinct from other Ferns ordinarily grown for decoration, they should prove very useful. I believe many of this genus would be more appreciated if they received more liberal treatment. A good rough compost, plenty of drainage, and sufficient surface room for the rhizomes to spread, with a genial atmosphere, will suit them well. There are many others worthy of reference which I hope to include in future notes. A.

STOVE AND GREENHOUSE.

RESTING ARUM LILIES.

At Heath Grange, Weybridge, the residence of Mr. W. A. Bilney, Arums are grown on the resting system, the results being in every way more satisfactory than when the plants are set out in the open ground for the summer months. Mr. Whitlock, the gardener, tells me that he could not get a good supply of flowers in late autumn and early winter until he gave the plants a thorough rest after blooming. They are placed in the open air at the foot of a wall, getting only enough water to keep the roots and crowns from shrivelling until September, when they are shaken out and repotted. Towards the end of October they commence to bloom, and continue to do so through the winter and spring months, some of the flowers measuring 10 inches across. The pots being well filled with roots early in the season, liberal feeding is practised, with the result that a

larger number of flowers of good quality is obtained than by any other method. I was told that plants which commenced to bloom early in November continued to do so freely until quite late in spring, and, what is more important, the plants every year exhibit a tendency to bloom at an earlier date than they have hitherto done. By planting out it has been found that only a limited number of flowers can be obtained at the time of year when they are most valuable; whereas when established and given liberal feeding, a succession may be obtained for some months. J. C. B.

Begonia Knowsleyana.—Among the many good things the genus contains this free-flowering kind is surely worthy greater consideration than it appears to receive. Its bushy form and great freedom as well as profuse flowering, to say nothing of the delicately toned flowers, should tend to its general use as a pot plant. As an autumn bloomer, too, it is of much value, and by a little attention the flowering may be extended a long way into the later months of the year. Given a course of similar treatment, it should prove a welcome companion to the charming *Gloire de Lorraine*, and it may be useful also to cross with the latter in the hope of raising others as good and free and of other shades.

Saintpaulia ionantha.—This interesting little plant is deserving of all that is said of it in the paragraph on page 439. It is particularly suited for small pots, and looks prettier thus than when grown in larger sizes. It can be propagated from leaf cuttings, that is, leaves with one or two transverse cuts across the fleshy midrib, and then pegged on the surface of a seed-pan or pot filled with fine sandy soil. In course of time a callus forms where the cut is made, and from this, little plants spring up. A moist shelf in a warm greenhouse seems an ideal place for this small, but profuse bloomer. It is seen in such a position to better advantage than if arranged among other plants.—S.

Dracæna Sanderiana.—I think this should make a useful plant for florists. One great point is that it retains its clear white variegation well, is easily propagated, and although it requires a stove temperature, it stands fairly well. When grown singly it is too slender as a pot plant, except when used in quite small pots. In a 5-inch pot three plants should be grown together. In propagating they should be put in singly into small pots and potted together after they are well rooted, selecting plants of as near the same height as possible. The same stock plants will give a good succession of cuttings if treated carefully. If allowed to make a good growth before taking the cuttings they will keep in health and give a succession, but when cut too close they are liable to lose their roots, and do not then start away so freely. A good loamy compost with plenty of drainage is necessary. In a moderate stove temperature it will make free growth and soon attain to a useful size.—A.

Salvia Hoveyi and others.—Recently I saw *Salvia Hoveyi* in fine condition in the conservatory at Frimley Park, the dark purple flowers harmonising well with red *Salvias* and white *Chrysanthemums*. The *Salvias* have much to recommend them for the decoration of the conservatory. *Salvia splendens* and its variety *grandiflora* are most useful in the autumn where bright flowers are in demand. *S. Bethelli*, again, is a good kind, although I have found this does not lend itself to late stopping, as does the old *splendens*. *S. Pitcheri* should be grown where a light blue is wanted. This kind is best from old roots, as it is semi-tuberous-rooted, and will stand in the open if planted in a warm, dry spot. If small plants are wanted for placing in vases for house furnishing, the best way is to strike four or five cuttings in a 4-inch pot at the end of June. When rooted, pot them on together and do not stop them. By so doing you get plants about a foot high. Another recommendation of these *Salvias*

is that they cost little to grow and continue in bloom a long time. They may be planted out and lifted in autumn.—J. CROOK.

FREESIAS FAILING.

I WILL thank you if you will let me know the cause of the enclosed Freesias going wrong, and whether you can suggest a remedy. The bulbs were planted in July in apparently good condition, and showed no signs of disease until about a month ago. These sent were planted in boxes in the usual compost of two parts old loam, one part sand, and one part decomposed manure, with a sprinkling of old lime mortar. There is another lot in a well-drained border against a south wall in the natural garden soil, which is very sandy, and these are also showing signs of going off. In the first batch about 20 per cent. is going off, but the remaining 80 per cent. is perfectly healthy and now showing buds.—W. M.

* * The plants sent are suffering from a disease that attacks the bulbs and ascends to the central core. By cutting open a few, it was noticed that the disease had extended from one-third to one-half in an upward direction, the root fibres as a result being discoloured. The disease is in effect somewhat similar to that attacking *Gladiolus The Bride*. Is it possible the Freesias have been grown on land where these latter have been grown and so become contaminated? So far as can be gathered, there is no error of culture, as by the plants growing in boxes all should fail should this be the case. The fact, too, that the failure only occurred recently, and that the crop in the open is similarly affected, points to disease in the stock rather than aught else. Were it otherwise and the portion in boxes diseased, it would appear the root-fibres had come into contact with some objectionable matter. Even now this may be so of the stock in both instances, though this may be determined by examining a few bulbs the moment the disease is first noted. Then if the root fibres were healthy save for the extreme points, the cause would be some deleterious agent in the soil. If the points of the roots are quite healthy at this stage, and the point of attachment with the bulb, as also the bulb itself, diseased, the fault rests with the bulb. The point is worth deciding, as the soil may be treated specially. If, however, the fault is with the bulb, as we surmise, the only remedy is to draw out and burn all affected plants.—Ed.

Jasminum Sambac.—This is well worth growing where heat and space can be afforded, its pure white flowers produced in small cymes being forthcoming the greater part of the year. It succeeds equally well planted in the border to cover a pillar, or grown in a pot and trained to a trellis. A suitable compost is sandy peat, fibrous loam, and decomposed leaf-mould in equal proportions, adding enough broken charcoal and sand to keep the whole porous.—J. L.

Andromedas as pot plants.—*Andromeda japonica* and its near relatives, *floribunda* and *speciosa*, have a very nice appearance when flowered under glass. Some years ago I had occasion to admire a tolerably large specimen of *A. floribunda* which in early spring occupied a prominent position in the show house of a local florist. It was always crowded with flowers and had a most attractive appearance. With a little care these *Andromedas* may be maintained in health for years in large pots or tubs, and may be used for decoration where more tender things would suffer. For corridors or similar places where little or no artificial warmth is maintained these charming evergreen-flowering shrubs are of great value. *A. japonica* forms its flower-trusses in the autumn and is apt to suffer in the open in severe winters. In a cool house it gets just the shelter it needs, retains its foliage in a fresh green condition, and expands its flowers at a very early period. All that the plants need during the summer is a little shelter from hot sun, with plenty of water in dry weather.—J. C., *Hyflct.*

TREES AND SHRUBS.

PAULOWNIA IMPERIALIS.

THE Paulownia as cultivated in Europe is made to serve two distinct purposes. It is grown in its natural form—a medium-sized tree with striking foliage and flowers of singular beauty. It is also grown in the sub-tropical garden, under special treatment, for the sake of its immense foliage only. An example of the latter method is shown in the accompanying illustration. Unfortunately, we in England but rarely see it in all its natural beauty. In the milder parts of the kingdom trees 30 feet to 40 feet high may be seen, but even there it does not flower with the regularity and profusion one notices in France, even as far north as Paris. In maturity the Paulownia may easily be mis-

the *Jardin des Plantes* at Paris; 150 terminal bunches, bearing each twenty to thirty flowers, make the tree appear like a single bouquet of light blue flowers." Those who have not seen it in flower will get the best idea of the beauty of the Paulownia by turning to THE GARDEN for April 2, 1892, where there is a coloured plate drawn by Mrs. Dalglish in a garden at Pau, in South-Western France. It forms its flower-buds in autumn, but they do not expand till the following May in France, not till June in England. They are borne on terminal racemes, and in shape are not unlike a *Thunbergia* flower or a very large Foxglove (it does, indeed, belong to the same natural order as the latter). The colour is a pale violet-blue. A fine specimen studded with its noble racemes is a most beautiful picture. The species is undoubtedly a native of China. Dr. Henry has

A group of *Paulownia imperialis* in the Royal Gardens, Kew. From a photograph by G. Champion.

taken for a *Catalpa*, having leaves of much the same size and character. In the early days of its cultivation in England *Catalpas* were frequently sold as Paulownia.

The first plant seen in Europe was raised by Mons. Neumann in Paris in 1834. It is not a true native of Japan, but the first seeds were sent from that country. Of these, however, only one germinated. The plant was carefully protected and at first housed in winter, but was soon found to be hardy in Paris. It first flowered in 1842. Referring to this plant a writer in the *Revue Horticole* for 1844 observes: "The parent of all the Paulownias, which have now been distributed through the gardens of Europe, has just flowered for the third time in

found it wild in various mountain localities. It has generally been considered a native also of Japan, but according to Professor Sargent it has only been introduced there. It is naturally a round-topped tree, 40 feet to 50 feet high.

To us, however, whose gardens are situated where the climatic conditions do not allow of the Paulownia being grown as a flowering tree—and this, of course, is due to lack of intense sunshine such as it enjoys on the Continent and to our treacherous springs—the mode of cultivation illustrated on this page is of more immediate interest. The photograph from which the engraving was made is one of a group of Paulownias in the Royal Gardens, Kew, where it is grown simply for the summer

effect of its foliage. The object is, of course, to get the leaves as large as possible. The plants are set out 3 feet to 4 feet apart, and are confined to a single stem. During one season this grows from 10 feet to 12 feet high, and is 7 inches or so in circumference at the base. The largest leaves measure 26 inches across. The treatment is as follows: Before growth recommences in spring the old stems are cut back to within 1 inch or 2 inches of the previous year's wood. Several young shoots start away, all of which except the two strongest are removed. These are left for a short time for fear of an accident happening to one of them, but as soon as they are well started the weaker one is cut off. The plants should be given a rich loamy soil to grow in, and a thick dressing of manure should be applied during the period of quickest growth, when frequent waterings also are beneficial if the weather be dry and hot. A group of plants thus grown makes a noble feature. The group illustrated is near the main gate at Kew, and there are others in a different part of the grounds. On Sunday afternoons in late summer, when the leaves have reached their fullest size, there is often a regular procession of visitors across the lawns to more closely inspect them.

P. imperialis is very easily propagated and can now be obtained cheaply, although in its early days as much as £5 was asked for small plants. It can be raised from root-cuttings taken off in spring as growth recommences; the roots should be cut into pieces 1 inch or 2 inches long and put into small pots of light soil plunged in a brisk bottom heat. Cuttings of the stem growth will also root readily when treated in the same way, but they have to be taken later, when the young shoots are a few inches long.

PAULOWNIA FORTUNEI is another Chinese species of which but little is yet known in Europe. It was described by Mr. W. B. Hemsley eight years ago in the *Linnean Society's* journal, and seems to have first been discovered by Robt. Fortune in some locality in China he did not record. It was not introduced till quite recently, when what is believed to be the plant has been received by M. Maurice de Vilmorin from China. It is now in cultivation at Kew. According to Mr. Hemsley, it is "readily distinguished from *P. imperialis* by its much elongated leaves, covered beneath with a pallid, almost white, very short, and dense tomentum, and by the longer, relatively narrower flowers and larger fruit." It is evidently a beautiful tree. W. J. B.

KITCHEN GARDEN.

EARLY RHUBARB.

EARLY Rhubarb is an important crop in most gardens, yet it is not always the best method is adopted for its production. A position shaded by trees or other objects is unsuitable for the growth of roots which are to be lifted for early forcing, although it may do very well for later kinds that are to make their growth under natural conditions. Few now-a-days, even where leaves are plentiful, care to force their earliest batches by means of pots and leaves, choosing rather to raise young stools annually or biennially, lift when two years old, and place in a Mushroom or forcing house. The position allotted to the seedlings should be an open, sunny one, so that growth may be matured early, but sloping borders should be avoided, as the roots in dry summers may require watering in order to prevent a premature ripening, as when this happens and a wet time follows a secondary growth is apt to start

rendering the crowns unfit for early lifting. Where practicable, it is a good plan to sow the seed in a frame in which Potatoes have been forced, as the gentle bottom-heat favours an early and strong growth. There are various kinds recommended for early work, but I am certain none is better than the true Prince Albert. I am not sure whether the variety named Royal Albert is the same, but the true sort forces so readily that I have seen it pushing through slight mounds of leaves and litter early in the new year. What I prefer is a heated pit in which a bed of leaves can be placed in which to plunge the stools. These also give off a genial moisture, and good flavoured sticks are produced. Old-fashioned vineries have sometimes a brick pit. This answers the same purpose. Failing either of these, the Mushroom house will grow it well. For pulling at the end of January and throughout February I prefer having a good-sized permanent bed of Prince Albert, so that one half can be forced one year and the other the next. If a good width is left between the rows and some 4 feet between each root, stout short stakes can then be driven in round each so as to form a square, these being encompassed with hay-bands to prevent the leaves falling on to the stools, and the intervening spaces filled in with leaves and linings built up at the sides. After laying a few leaves or a little litter over the crowns, small square lights made to fit exactly are laid on the top and the whole covered with straw. The lights can be easily removed for pulling, and when this is completed for the season, abundance of light can reach the stools to strengthen growth until the lights can be left off altogether. Prince Albert, although rather small, is of good colour and excellent flavour. Whatever variety is grown, it always pays for a liberal mulch, and, if time can be spared, one or two annual soakings with liquid manure.

N.

Sandringham Winter White Broccoli.—

This season the above Broccoli is good. The seed was sown in April, and the seedlings were ready to plant out before the dry weather set in. The plants, set out in rather firm land not recently manured, went away at once, and have given a fine crop of pure white heads, not large, but of excellent quality. In shape it is not unlike the old Snow's Winter White. The Sandringham is not a coarse grower. It is distinct in leaf and growth, being very compact, and gives a pure white head with close, hard curd, the leaves folding well over and protecting the flower.—G. W.

Cauliflower Mont Blanc.—Those who need early Cauliflowers will do well to add this. It is one of the best I have grown. Last season this was sown in heat to give a succession to the autumn-sown plants, and it did so well that I am giving it a trial sown in the autumn. Few growers are overdone with Cauliflowers in May, and I think Mont Blanc one of the earliest. The plants are very dwarf, not unlike the Dwarf Erfurt in this respect, but the foliage differs. The heads are pure white and of fine quality. This kind if sown in January may be had fit for use in the early part of June.—S. H. B.

Broccoli Michaelmas White.—For two seasons I have given the Michaelmas White a prominent place, and it is a very fine type. Some growers may think the heads too large in rich soil, but this can easily be avoided by cutting in a young state or by sowing a little later for October use. I sow in April for November supplies, or a little later for early winter. The plants may then be grown much closer together and will be of great value. At this season it may be necessary to lift when the heads are formed, but the variety named will remain good for weeks in a

cool cellar. The heads being pure white are of splendid quality, and come in well after the earliest varieties.—S. H. B.

New Pea Early Morn.—For sowing in pots, frames, or in the open ground for first supplies, Peas will now claim attention. For three seasons I have grown this variety and find it excellent in every way. Mr. Crawford some time ago wrote very highly of this new variety. Those who have grown the excellent Stratagem, one of its parents, will not be disappointed with Early Morn, as though lacking the size of Stratagem, the quality is as good and the gain in earliness is immense. It is a fine Pea for frame or pot culture, with true Marrow flavour, and being dwarf is doubly useful, as in pots it fruits freely and does not exceed 2 feet in height. Sown in pots at this season for planting out it will flower early in April and mature pods in May.—S. H. B.

Broad Beans in pots.—Those who like Broad Beans as early as possible may secure them quite three weeks or a month in advance of those raised in the open border if sown in pots now and wintered in cold frames. Many growers sow for an early supply in pots or boxes, mostly in the latter, but in January or February, and place in heat at the start. This I do not advise. Formerly I grew my earliest plants thus, but they suffer after planting out in severe weather. If grown quite cool from the start there is a sturdier plant and less trouble at planting, as, if well moulded up, they need no further shelter. I sow in November for May supplies, and in cold springs the produce even then may not turn in till early in June, but even then considerably earlier than from seed sown in the open. It is advisable to use 5-inch pots, not crowding the plants, growing near the glass in cold frames, and merely covering in severe weather. An Early Longpod is the best kind to sow. These plant out well. From boxes they do not lift so well, as the roots get matted.—S. M.

SOCIETIES AND EXHIBITIONS.

NATIONAL CHRYSANTHEMUM SOCIETY.

DECEMBER 6, 7, AND 8.

THIS show was distinctly above the average for the December meeting, and would have been still better but for the fact that during the last week so many excellent Chrysanthemums were lost through damp and fog, and on this account entries in some of the classes were not forthcoming. However, in many of the classes the competition was good. Japanese blooms, as usual, predominated, and those from the north left little to be desired in point of quality. There were some exceptionally good incurved and single-flowered sorts, and the vases of Chrysanthemums and foliage were also very good. Of the trade displays, two particularly good groups of blooms arranged in vases, &c., were the chief features. On this occasion the whole of the exhibits were arranged on the ground floor of the building, and in this way a far more imposing spectacle was presented to the visitors.

PLANTS.

On this occasion, the first for a long time, there was an entry in the class for six specimen single varieties, bush grown, trained or untrained, this coming from Mr. W. Davey, gardener to Mr. C. C. Paine, Hillfield, Haverstock Hill, N.W. The varieties were Kate Williams (two), a good rich yellow; Eucharis, pure white; Admiral Sir T. Symonds, and Earlswood, terra-cotta (two), a dull and dowdy-looking flower, these receiving first prize.

CUT BLOOMS.—OPEN.

There were no less than six competitors for twenty-four Japanese Chrysanthemums in not less than eighteen varieties, and not more than two of a variety. First prize fell to Mr. T. Lunt, gardener to Mr. Archibald Stirling, Keir House, Dunblane, N.B., with a remarkably fine stand of

blooms, beautifully fresh and highly coloured, and embracing a number of individual flowers of the highest quality. Specially good were Simplicity, Graphic, M. Hoste, John Seward, Mrs. F. A. Bevan, Matthew Hodgson, Niveum, M. Gruyer, Mary Molyneux, and Mrs. H. Weeks. Second honours were secured by Mr. R. Kenyon, gardener to Mr. A. F. Hills, Monkham, Woodford Green, Essex, also with a nice lot of flowers, including good blossoms of Etoile de Lyon, Matthew Hodgson, Iserette (a useful reddish brown), Oceana, Mme. Carnot, Papa Veillard, and John Pockett. For the prizes offered for twenty-four bunches of Chrysanthemums, any varieties, pompons allowed, to be set up in bottles, the five exhibits covered a large space and made a brave display. Large, bold, handsome blooms secured first prize for Mr. W. Howe, gardener to Sir Henry Tate, Bart., Park Hill, Streatham Common, who might have improved his arrangement of the flowers and also have named them. Etoile de Lyon, Niveum, and bold incurved blooms of The Egyptian stood out prominently. Second prize was well merited by Mr. Norman Davis, Framfield, Sussex, who had a pretty lot of blooms embracing large exhibition flowers of Mme. Carnot, G. J. Warren, and Western King, and a nice variety of decorative sorts of good colour, such as Tuxedo, the most useful of the clear bright bronze-coloured December sorts, and King of the Plumes, a rich yellow. There were nine competitors in the class for twelve Japanese blooms, distinct, Mr. Lunt again leading with a bright, clean, fresh lot of flowers, including well-developed specimens of Louise, Edith Tabor, Matthew Hodgson, Graphic, Oceana, Simplicity, M. Gruyer, Australie, and Niveum. A good second was Mr. R. C. Norent, Broughton Nursery, Ipswich, who had smaller flowers, but very fresh and neat. Master H. Tucker, C. W. Richardson, G. J. Warren, Nyanza, and Admiral Avelan were his best kinds. An entry of eight for six Japanese distinct was another good class, premier honours resting with Mr. J. Sandford, gardener to Mr. G. W. Wright-Ingle, Woodhouse, Finchley, with a meritorious stand containing good examples of Silver King, C. W. Richardson, Mme. Carnot, Golden Gate, Simplicity, and G. J. Warren. A very close second was Mr. Lunt, who staged handsome blooms of Matthew Hodgson, G. J. Warren, Simplicity, and Australie. A display of a high order of merit was seen in the class provided for twelve incurved, not less than six varieties and not more than two of a variety. It is doubtful whether a better lot has ever been staged at any previous exhibition. In this class Mr. F. King, gardener to Mr. A. F. Perkins, Oak Dene, Holmwood, Surrey, was first with notable examples of Mlle. Lucie Faure, Miss Violet Foster, l'Amethiste, The Egyptian, Bonnie Dundee, Lord Rosebery, and Miss Phyllis Fowler. Second prize was won by Mr. F. G. Foster, Brockhampton Nurseries, Havan', also with a handsome lot of blooms, but less even and regular. For twelve bunches Japanese, staged in bottles, Mr. R. C. Norent appeared to be the only competitor and was awarded first prize. Silver King, Lady Northcote, Mrs. Malin Grant, Matthew Hodgson, Golden Gate, C. W. Richardson, and Etoile de Lyon were the best. Of the three competitors for six bunches Japanese, Mr. John Heath, gardener to Mr. A. W. Chapman, Crooksbury, Farnham, was a good first, having fresh flowers of Oceana, M. Gruyer, Australie, and Western King. Second prize was awarded to Mr. George Elder, gardener to Mr. J. Benson, The Oaks, Walton, near Epsom, who had smaller, yet pleasing flowers. The display of large flowered single varieties was specially good. The chief class was for twelve bunches large-flowered, three blooms in a bunch, and arranged in vases. Mr. G. W. Forbes, gardener to Mme. Nicols, Regent House, Surbiton, secured leading honours with some of the finest blooms we have seen, Admiral Sir Thos. Symonds, Rudbeckia, Victoria, Purity, Tu-cola, Earlwood Glory, T. Grant, and J. Arter being well represented. Second prize was awarded to Mr. A. Felgate, gardener to Her Grace Eliza-

beth, Duchess of Wellington, Burhill, Walton-on-Thames, who had smaller, though very charming blossoms. Mr. G. W. Forbes again led in the class for twelve bunches small-flowered single varieties, setting up most delightful little blossoms of Little Pet, Mrs. D. B. Crane, one of the prettiest; Annie Tweed, Alice, Nora and Miss Mary Anderson. Had these smaller flowers been set up in bunches of six the effect would have been still better. Second prize was secured by Mr. W. C. l'agram, gardener to Mr. J. Courtenay, The Whins, Weybridge, Surrey, with a neat lot of flowers. Of the three competitors for six bunches large-flowered singles, Mr. A. Felgate, jun., nurseryman, Hershams, Walton-on-Thames, was first, staging Captain Felgate, Mrs. Felgate, Yellow Giant and Duchess Elizabeth in fine form. To Mr. J. Tullett, gardener to Mr. G. Alexander, Warley Lodge, Brentwood, second prize was awarded, his best flowers being Rudbeckia, Etilie, Golden Star, Geo. Rose and Kate Williams. Mr. Tullett also led in the class for six bunches small-flowered singles with a pretty lot of blossoms. Second honours were awarded to Mr. A. Page, gardener to Mr. A. L. Reynolds, Ravenscroft, Moss Hall Grove, Finchley, N., with a useful lot, but unnamed. A goodly entry was forthcoming in the competition for a large vase of Chrysanthemums arranged with any kind of foliage, grasses or berries. In this Miss Easterbrook, The Briars, Fawkham, Kent, excelled, arranging with perfect taste an immense trumpet vase with large yellow and white Chrysanthemums, relieved by a few sprays of the pretty little spidery flowers of the yellow Mrs. Filkins and pompon Snowdrop. The arrangement was finished with trailing growths of Asparagus and Smilax. Second prize was awarded to Miss C. B. Cole, The Vineyard, Feltham, with a much smaller arrangement, and in which a proper finish was hardly followed. A pretty feature of this exhibition is a class for a hand-basket of natural autumn berries and foliage. In this Miss C. B. Cole was first with a bright and charming arrangement of berries and foliage, the former predominating. Mr. A. Newell, gardener to Sir Edwin Saunders, Fairlawn, Wimbledon Common, was a good second, having a great wealth of berries, but lacking the artistic finish which characterised the leading exhibit. For the special prizes offered by Mr. C. W. Richardson, Sawbridgeworth, for twelve Japanese distinct, open to single-handed gardeners only, there were three exhibitors, each of somewhat poor quality. First prize fell to the lot of Mr. A. Honey, gardener to Mr. G. H. Cox, The Grange, East Barnet, and second prize was awarded to Mr. E. Bush, gardener to Mr. W. T. Lister, Rose Hill, Totteridge, Herts.

AMATEURS.

For twelve Japanese blooms, distinct, Mr. W. Perrin, gardener to Mr. C. W. Richardson, Sawbridgeworth, was first with clean, neat, though small flowers, Master H. Tucker, Mme. Carnot and Viviani Morel being his best examples. Mr. H. Love, Melville Terrace, Sandown, Isle of Wight, was second, deep coloured flowers, such as John Neville, Matthew Hodgson, predominating. For six Japanese, distinct, Mr. L. Gooch, gardener to Mr. T. Wickham Jones, was first, his stand containing blooms of Lady Hanham, Mme. Carnot, Mlle. Thérèse Key and a phenomenal bloom of G. J. Warren. Mr. W. Perrin was second with a somewhat dull stand of blooms. For a large vase of Chrysanthemums, Mr. l'agram was first with a charming lot of flowers, but set up without any attempt at a proper finish, and Mr. A. Page was second with a somewhat informal arrangement. For *boni-fide* amateurs, three classes were provided, a class for six Japanese, not less than four varieties, bringing out five competitors. Mr. G. C. Farmer, Leeds Abbey, near Maidstone, was first with a splendid stand of flowers, his G. J. Warren, Mme. Carnot, Mons. Gruyer and M. Demay-Taillandier calling for notice. A poorer lot of flowers secured second position for Mr. F. Durrant, 4, New Road, Ware, Herts. In the class for a large vase of Chrysanthemums, Mr.

D. B. Crane, 4, Woodview Terrace, Archway Road, Highgate, N., was first with a charming vase of the curious little Japanese Mrs. Filkins, interspersed with a few sprays of the yellow Snowdrop and a single or two. Second prize was awarded to Mr. A. Taylor, 5, Vernon Terrace, East Finchley, N., with a nice bold arrangement.

MISCELLANEOUS PLANTS.

There was a falling off under this heading as compared with other years. In the class for a collection of Cyclamens, Mr. William Orpwood, Andover Nursery, Uxbridge, was the only competitor, first prize being awarded to him for a large table of grand plants, freely flowered and also of good quality. Mr. Orpwood also was the only competitor for a collection of Primula sinensis, staging a nice lot of fairly well-flowered plants. By far the prettiest class under this heading was that for a table arranged with a collection of flowering, berried and fine-foliaged plants on a space 9 feet by 6 feet. A magnificent table arranged by Mr. A. Newell easily secured leading honours, this being carried out with great taste, and included pretty examples of Bouvardias in varying shades of colour, Roman Hyacinths, Poinsettias, Cyclamens, Begonia Gloire de Lorraine and other flowering plants, charmingly associated with neat and pretty specimens of Cocos Weddelliana, Crotons, Dracenas, &c., with Panicum variegatum and other plants of a similar description overhanging the edges of the table in a delightful manner. Mr. Howe was second with a table of plants of high quality, but not so well set up and embracing a too liberal use of Begonia Gloire de Lorraine.

MISCELLANEOUS EXHIBITS.

A large gold medal was won by Mr. Norman Davis, Framfield, for an immense table arranged across the building, draped in green, and upon which large oriental and other vases, hand-baskets, and designs were pleasingly and artistically disposed. Huge blooms of Mme. Carnot and G. J. Warren were the chief points of merit in the vases and in the stands, not the least important being the charming variety of decorative Chrysanthemums utilised, including such sorts as Tuxedo, King of the Plumes, Framfield Pink, Mme. Felix Perrin, Mrs. J. Carter, and many others. Individual blooms of novelties were also disposed along the front. A gold medal was also secured by Mr. H. J. Jones, Ryecroft Nursery, Hither Green, Lewisham, S.E., for an equally fine group. The vases of blooms, which were very numerous, were arranged with considerable taste, and the table was faced with some fourteen dozen flowers of leading novelties and standard Japanese sorts, including G. J. Warren, Julia Scaramanga, Western King, President Bevan, Pride of Ryecroft, Mlle. Laurence Lede, and Iserette. Messrs. H. Cannell and Sons, Swanley, had a long table either end filled with a group of Begonia Gloire de Lorraine and other winter flowering Begonias. Some sixty bunches of zonal Pelargoniums in wonderful variety of colour were very striking. In addition there was a pleasing assortment of decorative Chrysanthemums, including the white Mrs. Filkins (Mrs. Harvey), well meriting the gold medal this exhibit gained. Mr. Robt. Owen, Maidenhead, also had a good display of Chrysanthemums on boards and in vases, many excellent and promising seedlings finding a place. Mary Molyneux and Mr. M. Versfield were conspicuous in this exhibit (silver-gilt medal). Mr. T. S. Ware, Ltd., had a small table of Chrysanthemums, and Mr. A. Felgate, Jun., Hershams, a group of his Red L. Canning, a grand reddish crimson for late work. The Iethemic Guano Co. and Lawes' Manure Co. each had a useful exhibit, nor must we omit to mention the pretty rustic table decorations put up by Mr. T. Williams, 4A, Oxford Road, Ealing.

FLORAL COMMITTEE.

On Tuesday last the floral committee of the above society held its final meeting for the pre-

sent season at the Royal Aquarium, Westminster, Mr. T. Bevan occupying the chair.

Only two first-class certificates were awarded, viz., to—

CHRYSANTHEMUM MME. R. CADBURY.—A Japanese of large size, and with long close florets of medium width, slightly curly at the tips and drooping. The blooms are deep in build and of good substance; colour pale creamy white. Shown by Mr. H. Weeks.

CHRYSANTHEMUM RED L. CANNING.—A Japanese, a late free-flowering decorative variety, with flat florets of a rather sombre chestnut-crimson. From Mr. A. Felgate, jun.

Among others worthy of mention were J. R. Upton, a fine colonial-raised yellow Japanese of great size, which the committee asked to see again; Mrs. T. Dalton, another of the same section, very large and attractive, colour deep golden yellow, flushed carmine; and a large white variety called Mrs. N. Simpson. The committee next arranged its series of meetings for 1899, which are fixed as follows: September 27, October 10 and 25, November 1, 15, and 22, and December 5. It was also arranged that the annual dinner of the committee should take place on Monday, the 12th instant. The classification committee will also hold a meeting at the same time.

The annual dinner of this society was held in the Crown Room of the Holborn Restaurant on Wednesday, the 30th ult., Sir Albert K. Rollitt, M.P., in the chair. Ladies for the first time were present, and a very successful and enjoyable gathering it was.

After the toast of "The Queen and Royal Family" had been duly given and honoured, Mr. Percy Waterer proposed "The Donors of Special Prizes," reminding the company of the fine exhibits and keen competition in the class for twenty four cut blooms of Japanese for the prize offered by the Royal Aquarium Co., and also referred to the special prizes given to the society by Messrs. H. J. Jones, Deverill, Sutton, Sydenham, and Richardson. Mr. Waterer then proceeded to comment on the Chrysanthemum rust, and said he would offer £5 5s. for a good essay upon the fungus. The toast was replied to by Mr. J. W. Wilkinson and Mr. H. J. Jones. The next item on the programme was the presentation, by the chairman, of the national challenge trophy to the secretary of the Portsmouth and District Chrysanthemum Society, the Holmes Memorial cups and medals won at the recent November show, which furnished the chairman with several opportunities of displaying his ability to interest and amuse the company in a manner seldom experienced at the annual dinner. The toast of the evening was that of "The National Chrysanthemum Society," which was proposed by Sir Albert in a peculiarly happy mood. He referred to the time in 1884 when, as Mayor of Hull, he opened the first Chrysanthemum show there, and expressed his pleasure in finding that there were present several of his fellow-townsmen that evening. He considered it a public duty to recommend the cultivation of flowers, as it was the purest and highest form of enjoyment. Speaking of the Chrysanthemum, he said it was a plant well worthy of the care that had been bestowed upon it. To a large extent it had remained stationary in its old home in China, but how wonderful had been its improvement when once introduced into a civilised nation. The chairman then compared the old Tulip mania with the present widespread interest in the Chrysanthemum, and expressed his pleasure that it had never reached the stage of speculation that the Tulip had in days gone by, and which had to be suppressed by Government. He also remarked upon the progress of the society since its early days in the north of London, and said he could only regard it as an excellent national institution and hoped that it might continue to flourish. The toast was received with acclamation. Mr. E. Harland, of Hull, proposed "The Presidents, Vice-Presidents, Officers, Auditors, and Com-

mittees," and this was responded to by Mr. C. Harman-Payne and Mr. A. E. Stubbs.

The chairman's opportunity of proving the fitness of his selection was again fully exemplified when he rose to propose "The Ladies," which he did in his happiest vein. Mr. Leonard Brown responded. Then Mr. T. W. Sanders gave "The Chairman," and in the course of his remarks called attention to the many positions of public importance that Sir Albert occupied, and expressed a hope that he would be present at a future meeting. Sir Albert replied, thanking those present for the cordial reception they had given him. Gardening, he said, was part of his every-day recreation. He had visited their show at the Aquarium, and was pleased with what he had seen there. "The Press" was proposed by Mr. R. Fife, and responded to by Mr. George Gordon, who reminded them that much of the popularity that the society enjoyed was due to the press.

There was a large company present, numbering in all 113 persons, and the fair sex was well represented. The tables were tastefully decorated with cut Chrysanthemums, arranged in some large Japanese vases kindly lent by Mr. H. J. Jones. The musical arrangements were under the charge of Mr. A. Taylor.

Royal Horticultural Society.—The last meeting this year of the Royal Horticultural Society will take place next Tuesday, the 13th inst., in the Drill Hall, James Street, Westminster, when the fruit, floral, and Orchid committees will meet as usual at 12 o'clock. A lecture on "Some of the Plants Exhibited" will be given by the Rev. Geo. Henslow, M.A., V.M.H., at 3 o'clock.

NOTES OF THE WEEK.

Violet Princess of Wales.—The newer kinds of sweet Violet add very much to the interest of a very ancient culture, and this bold kind is sent us in a fine state by Mr. J. Barn, florist, of Cramer.

Diosoyros Kaki (Date Plum).—A specimen of this interesting Japanese tree is now carrying a crop of its large and handsome fruits in the large succulent house at Kew. The largest fruits are the size of a good-sized Orange, and at a short distance not unlike it in colour. Unfortunately, at this stage the tree loses its leaves, otherwise its attractiveness would be increased.

Dianthus pinifolius.—Till the heavy and almost continuous rains of the past few days began, this pretty Grecian Pink was flowering freely in the open. The plant, in the clustered heads of flowers, may be likened to a small form of *D. cruentus*. In height, however, it is not more than half of the last-named, or about 8 inches. The very compact tufts are, however, crowded with the spikes of flowers of a lilac-purple shade. In the fineness of its foliage it resembles the minute Pine points; hence probably its specific name. It is an interesting as well as free-flowering alpine.

Galanthus species from Albania.—The second Snowdrop to flower this season here has been one of several received by way of Holland as "species from Albania," probably *Galanthus octobrensis*. I have had these Snowdrops for several years and they have proved as a whole fairly good growers. The one now in bloom was selected two years ago and placed by itself. It opened on December 2. Snowdrops are as a rule not making so much progress as one has seen in some former seasons.—S. ARNOTT, *Carslhorn, by Dumfries, N. B.*

Crassula Saxifraga.—The dainty white, pink-tinted blossoms of this pretty species above the somewhat fleshy and nearly orbicular leaves appear in striking contrast, and form one of the prettiest objects now open. The smooth, spreading leaves cover the whole surface of the soil, the small scapes arising in the midst and bearing several of the pretty blossoms in an umbel. The whole plant is not more than 4 inches or 5 inches high, yet sufficiently attractive to at once catch the eye. It should prove a charming

companion plant to *Santpaulia ionantha*, though the latter is more spreading.

Solanum macrocarpum.—This may be counted among the more attractive as well as interesting species of this genus, the smooth and rounded fruits being about 1½ inches in diameter. The habit of growth is very distinct, the plant being studded with spines all along the stems. The rather shapely fruits occur at intervals on the branches and are of a dull red shade. Another species also fruiting at the present time is *S. integrifolium*. In this the fruits are considerably corrugated. This kind, however, has more highly-coloured fruits, these inclining to scarlet. Both species are fruiting at Kew in the large greenhouse at the present time.

Calluna vulgaris aurea.—The hardy Heaths are all very beautiful in winter, their foliage doing much to redeem many parts of the garden from their wintry bareness. This variety of *Calluna* (or *Erica*, so called) *vulgaris* is distinct from the others by reason of the golden colour of its young growths. The term "golden" is perhaps rather far fetched, but one can hardly find a better word for the bright yellow-green of this Heath. A good contrast is afforded by the deep green of *C. vulgaris Foxii*, which I have growing alongside *C. v. aurea*. *Erica mediterranea alba* has its branches already bearded with flower buds.—S. ARNOTT, *Carslhorn, by Dumfries, N. B.*

Hyacinthus amethystinus.—The only reason for naming this plant at this time is to urge the planting of it in quantity in the open border or the woodland. The species is somewhat late flowering, usually from the middle to the end of May, but the beauty of the plant is sufficient guarantee for its being grown by the hundred or thousand, instead of as now being rarely seen. Indeed, the lateness of its flowering is valuable in extending the season of such things in the open ground. The pretty shade of blue seen in the flowers is well conveyed in the specific name. There is also a white variety equally good if less plentiful. Both kinds may be had at a cheap rate in the dry state, and established in the garden are very effective.

Senecio macroglossus (African or Ivy-leaved Ground-el).—The genus *Senecio* is perhaps among the most varied of any that could be named. Take the above named plant and compare it with the Rush leaved Ground-el (*S. junceus*), *S. grandifolius*, or the well known perennial kind, *S. pulcher*, and you have a set of species bearing externally no evidence whatever of the relationship that exists between them. As a greenhouse climber the species above-mentioned is a very pretty and pleasing object. Very pretty, too, are the Marguerite-like blossoms, likewise distinct in colour, a sort of chrome-buff shade pervading the ray florets. These forming the flower-head are about 2 inches across, and if not particularly abundant, occur with sufficient frequency to make the plant a useful subject in the greenhouse.

Eugenia Ugni.—I enclose fruiting branches of *Myrtus Luma* (*Eugenia apiculata*) and *Eugenia Ugni*. I wish to call your attention to them, as I think their merits are not sufficiently known. *E. Ugni* never fails to bear a profusely abundant crop of very pleasantly flavoured red berries which, to my thinking, make an excellent tart. I have had about a dozen of these since summer, and can speak of their value. One bush is about thirty years old, but a younger one, in peatier soil, bears a better berry. *E. Luma* has a larger (black) berry, good enough to eat, but is not so good as the other in pastry. It is a more beautiful Myrtle than *Ugni* in flower, the flowers being larger and purer white. It is a lovely thing. Both seem very hardy, never suffering in any weather here, as the common Myrtle sometimes does.—H. C. HART, *Dublin*.

Ornamental Vines.—I was very much interested in Mr. Bean's paper on these graceful plants, and should like to hear from whence cuttings of the old variety of hardy or open air Grape called Dusty Miller, or Miller's Burgundy, can be obtained. As to the Japanese *Vitis Cignetia*,

it seems to be very variable from seed, some of the forms having no trace of the wash-leather-like tomentum behind the leaves. In pots or small tubs of loam, lime rubbish, and wood ashes it colours finely in a cool house, or, if not too liberally treated, on a S.W. wall. The Claret-leaved Vine, where it grows well, is one of the finest of all in colour, darker and richer than the Tinturier forms, which have more or less marbled foliage. Apart from fine-foliage effects, some of the wild Vines from America have very fragrant flowers and their fruit is ornamental.—F. W. BURBRIDGE.

Bomarea Carderi.—It may not occur to growers of hardy plants how very closely the flowers of some species of the above genus individually resemble the *Alstromerias*, yet if a bloom be examined the shape and the curious markings will be found in general agreement with those of the hardy plants named, or at least some of them. One point, however, possessed by *Bomarea* is lacking in the other group, viz., the long time the former remain in flower. Frequently this may be counted by weeks, and as the number of flowers is large the flowering example is attractive a long time. This is a valuable item in a group of plants so generally easy of culture. In the species named the flowers are long and pendulous, the outer segments rose, and the interior freely spotted with purple and brown. It is a native of Colombia.

Primula Forbesi.—The profuse flowering so characteristic of this pretty species is even now shown by the constant endeavour of the plants to send forth spikes of bloom. Remembering, too, the varied character of the weather during recent weeks, the above fact speaks as much for the generally hardy nature of the plant as its persistency in flowering. Indeed, all that is needed to prolong its flowering in southern gardens is a sheet of glass to throw off wet from constant rains. Several of the *Primulas* are nearly perpetual in their flowering, and as much may be said of this pretty kind. The plant, too, that remains in flower several months of the year is one to be specially valued, and when, like this, it may also be freely and easily raised from seeds, it is of greater value still. Freely grouped in the rock garden, Forbes's Primrose is an interesting feature for a long season.

The Strawberry trees.—Both *Cornus capitata* (= *Benthamia fragifera*) and *Arbutus Unedo* have been very fertile and beautiful in Ireland during the autumn and early winter. At Bantry, Fota, Cork, Limerick, and in Wicklow I hear these plants have fruited most luxuriantly, and even near Dublin, and especially at St. Anne's, Clontarf, the *Arbutus* has been laden with its glowing red fruit and pale waxy flowers. Both plants are so quickly and easily reared from seed, that the wonder is they are not more largely grown in the west and southern districts of England, Wales, Ireland, and Scotland, especially in sheltered localities on soils that suit their growth. *Arbutus Unedo* grows so well on the islets at Killybeg, that I often regret that the larger and rarer kinds, such as *A. Andrachne*, *A. hybrida*, *A. procera*, and *A. Croomei*, are not also planted there.—F. W. BURBRIDGE.

Lenten Roses (*Helleborus orientalis*).—These plants promise to be very early this season, some seedling forms being in bloom at present along with the forms of *H. niger*, or true Christmas Rose. Some years ago I attempted to cross the great white *H. orientalis*, a noble plant long grown here as *H. olympicus*, with the large early form of *H. niger* called *maximus* or *altifolius*, and one of the resulting seedlings is now in flower. I should not like to say that it is a cross between the two species, and yet it is different in habit and time and mode of flowering from any true Lenten Rose known to me. The flowers are white, borne on long-branched spikes, the flower-stalks being deeply stained with brownish purple. These flower-stalks keep on branching, and will keep up a succession of bloom till next March or April. The heavy rains we have lately had will help Lenten Roses wonderfully, and if the weather

continues mild we shall have a good bloom this season—one of the best for years.—F. W. B.

Galanthus nivalis octobrensis.—Though accredited with being an October flowering species, it is but rarely, if at all, it blooms then. It is, however, no less welcome in mid-December than in October. Of the winter Snowdrop a pretty handful may now be seen at Kew in the hardy plant department, where a cluster is bearing some eight or nine of its blossoms. This, I believe, an increase on the number of flowers a year ago, but in any case the variety is not noteworthy for its vigour or rapid increase. Frequently in a semi-wild state the common Snowdrop is more vigorous when the bulbs are associated with the roots of some miniature shrub. The root-fibres of the latter take up much of the superfluous moisture that envelops the bulbs during their long dormant period, and which can scarcely benefit the bulbs for so long a time. A similar plan may be worth trying in connection with the above.

Anomatheca (Lapeyrousia) cruenta.—Those who have gardens in mild districts or on light soil might do worse than try a few bulbs of this bright coloured plant. One would not like to say that it is perfectly hardy, as that would be misleading, but it might be tried with advantage in more gardens than at present. In June it is one of the many features of interest in Trinity College Gardens, Dublin, where Mr. Burbidge finds it do well, and where it shows to more advantage in the shade than in full sun. The colouring, with the deep blood-red spot at the base of the segments, looks much brighter in the shade. This South African Irid is now very cheap, and a few bulbs procured and planted after the turn of the year might prove a good investment for some. I grow it here both at the base of a warm wall and in the shade. It is difficult to say whether it looks better by the wall or in the shade. It is later in coming into bloom in the latter position.—S. ARNOTT, *Carsuithorn, by Dumfries, N.B.*

Hedera obovata.—Now that deciduous creepers and climbers have lost their foliage, the Ivies and others of evergreen habit become of special interest to those who devote themselves principally to open-air gardening. Among the most distinct of the Ivies is that known as *Hedera obovata*, which one finds referred to *Heptapleurum stellatum* in "Index Kewensis." Its small leaves, whose form is fairly well indicated by the specific name *obovata*, look well on the wall. Collections of Ivies are not often seen, but one is pleased to observe an increasing interest being taken in them. This year I have been in several gardens where collections were being brought together. At Rockville, Murrayfield, Edinburgh, Mr. P. Neill-Fraser has a number growing on trees. They are kept within bounds so as to prevent injury to the trees, and on the occasion of my visit last year formed a feature in a very interesting garden. The one referred to was one of those to be seen there. It is not a rare Ivy, but, all the same, it is not plentiful enough.—S. ARNOTT.

Epiphyllum truncatum.—A particularly fine example of this may now be seen in flower in the large succulent house at Kew. The plant is of exceptional size. The example in question is apparently grafted on a vigorous *Pereskia* stock, which alone appears upwards of 3 feet long. The dimensions of the plant, however, roughly taken will give an idea of the example in question; height from ground nearly 6 feet, diameter of head of branches between 3 feet and 4 feet, a similar space being occupied in the depth of the head, a portion having assumed the ascending and another a drooping position. The health of the plant is remarkable. It is growing in a pot about 18 inches in diameter and has borne a sumptuous array of blossoms. The plant is growing in what appears to be a rather heavy loam, and its present fine health may largely be traced to the careful attention the plant has received from the first. Such things only need to be overwatered

once or twice to bring about their ruin. The roots these plants produce are somewhat meagre, nor does the plant, by reason of a naturally succulent nature, assimilate much moisture. Such excellent examples of good culture are by no means common.

Name wanted.—A relative of mine living at Ningpo, in China, sends me a drawing of a plant growing in his garden which he wants to obtain the name of. He is a good draughtsman, so one may take the figure as correct. The plant appears to be nearly allied to the *Arums*; the spathe is long and narrow; the leaf, which is on a long stalk, is divided into three lobes. The interesting part about the plant is that the leaves bear bulbils or adventitious buds, somewhat similar to those in the axils of the leaves on the flower-stalks of some Lilies. In the plant in question, where the trifid leaf joins the leaf-stalk there is a bulbil, and there is another about half-way down the leaf-stalk which seems to force its way through the skin of the stalk, which is somewhat kneed at that point. I should be very much obliged to anyone who can give me any information about this plant.—G. S. S.

Outdoor labels.—I suppose zinc labels would be cheaper than anything for permanent outdoor work, and they are especially handy on herbaceous borders where it is found advisable to name the different clumps of flowers. The best of them answer the purpose very well indeed, and I have some at the present time, the patent of a writer on hardy plants well known to GARDEN readers, that were written four years ago and still quite clear. Others are not so good; the zinc to outward appearance is brighter than in those named above, but the first rain brings out a scaly matter on the metal sufficiently pronounced to partially obliterate the writing. Each of the types of label was worked in the same way. I cleaned them with fresh ammonia and lettered them with the indelible ink sold for the purpose. There is a great variation in the sheets of zinc, but so far as the material of which labels are made is concerned, I think those responsible for their production should see that it is practically impervious to weather. It is not very pleasant after writing a lot of labels and placing them in position to find after the first rain that it is impossible to distinguish the lettering.—E. BURRELL.

The weather in West Herts.—An extraordinarily warm week for the time of year. The highest temperatures registered during the week were about 10° warmer, while the nights were as much as 14° warmer than their respective averages for the previous twelve Decembers. In fact, on only one night was the lowest reading colder than would have been reasonable in the warmest part of an average December day. On the night preceding the 5th the thermometer exposed on the lawn never fell lower than 51°—making this the warmest night I have yet recorded here in the same month by 5°. The ground at the time of writing (7th inst.) is exceptionally warm, being about 7° warmer than is reasonable at 2 feet deep, and about 8° warmer than is reasonable at 1 foot deep. Rain has fallen during the week to the depth of nearly an inch, but very nearly the whole of that amount fell on the 6th. The weather since the beginning of the month has been extremely gloomy. On three days no sunshine at all was recorded, and on three others there was less than an hour's sunshine. The wind has been, as a rule, high, and the direction always some point between south and west.—E. M., *Berkhamsted.*

Name of plant.—*P. Bosanquet.*—The Turkey Oak, or one of its varieties.

Names of fruit.—*W. Plant.*—1, 4, and 5, King of the Pippins; 3, Worcester Pearmain; 7, Norfolk Beauty; 8, Rymer; 12, Sturmer; others not recognized. We only undertake to name four varieties of fruit in any one week, and it is always advisable to send two typical specimens.—*T. W.*—1, Cox's Pomona; 2, probably Roundway Magnum Bonum; 3, Yorkshire Greening.

ORCHARD AND FRUIT GARDEN.

FEEDING PLUM TREES.

CORDON Plum trees are sometimes apt to make too strong growth. Lifting and shortening the strongest roots and transplanting them will rectify this, and once they commence to bear they do not often get out of bounds again, but if they should, the remedy lies in the grower's hands. Even fan-trained trees are frequently disposed to make rank, unfruitful growth, but in this case also lifting as advised for cordons will prove a corrective. Much may be done at planting time to prevent trees making exuberant growth by using calcareous matter, which should be mixed liberally with the compost if a new border has to be made, and with the staple when the soil is naturally rich and fertile. On no account use farmyard or other organic manures at planting time even if the soil is of a poor description, as these are almost sure to bring about unsatisfactory results. For poor soils or those in need of manure, bone-meal may be used with advantage, afterwards feeding the roots from the surface. Although advocating a let-alone policy with regard to the use of organic manures at planting time, I strongly favour their use after the trees have begun to bear, as it is then the latter need assistance. Too often one sees trees literally starved in this respect, and the Plum receives less attention than any other fruit tree. Farmyard manure may be used for top-dressings, while that from the stables makes a capital summer mulch. Artificial manure may be given when the two last-named cannot be afforded. A mulching of some description is useful, especially on warm gravelly soils, as, besides keeping the surface cool and preventing too rapid evaporation, it lessens the need for artificial watering in a dry season. Superphosphate of lime is excellent for Plums, and kainit is also highly recommended, the quantities to use being 2 ozs. of whichever is

given the preference, per square yard. For assisting heavily laden trees to carry through and perfect their crops, liquid manure, bone-meal, and dried blood in combination, guano, and nitrate of soda are useful. The nitrate may be applied at the rate of 2 ozs. to the square yard after the fruit is set, this being repeated after the fruit has stoned and is taking the final swelling. Guano and the other two manures mentioned need not be weighed, as sufficient may be given of either just to colour the surface-soil at each application. Liquid manure may be given as often as moisture is required at the roots, diluting it or not as the case may demand. Manures of any description should, of course, only be applied either at the time the trees are bearing or after the trees have borne heavy crops. On some soils root-watering must have attention in hot, dry seasons if fine juicy fruits are looked for, and an occasional hosing will also tend to keep the foliage clean. Insect attacks, to which Plums are very susceptible, should always be dealt with promptly, as once they gain a footing and the leaves become curled it is almost impossible to reach them with insecticides. Thoroughly cleaning the trees during the winter months goes a long way towards preventing such attacks. No insecticide, in my estimation, equals the wash made with caustic soda and crude potash.

A. W.

Gros Colman Grapes colouring badly.—Redness in Gros Colman Grape is this season very common. There seem to have been too much strong sunlight and heat; perhaps also, in consequence, none too much root moisture. But the Muscat of Alexandria does not require too much root moisture and like plenty of light and warmth, hence the berries generally have coloured well. Gros Colman rather likes some shade, but the foliage often begins to fade or discolour early, and when that is so it seems as if colouring matter were directed from the berries to the leaves. Happily, with this Grape blackness of colour is not always associated with the Grape's best flavour, which is never very great. But well-

grown, yet reddish berries often are for the variety the best flavoured.—A. D.

Colour in Muscat Grapes.—Although the competition in Muscat Grapes at the recent Royal Aquarium show was very limited, it was very satisfactory to find that the judges distinctly favoured finish and colour over mere size of bunch. The exhibitor of the largest bunches, certainly a capital grower, had handicapped his exhibit by not thinning sufficiently in the earlier stages of growth. The result was some fine outer berries, very well coloured, and some much smaller ones that were comparatively green. The smaller bunches placed first and second showed very rich golden amber hue and fine finish. It was satisfactory to see due regard paid to these merits. So frequently mere size of bunch weighs with judges, that the greatest merits of Grape culture are often overlooked.—A. D.

Netting indoor Peach trees.—Although Peach trees carrying ripe and ripening fruits may be gone over every day for the purpose of gathering those that are fit, a few will be sure to fall in the interval. When these come into contact with the hard ground they are spoiled either for private use or market. It is an easy matter to suspend some soft material beneath the tree to catch falling fruit. Fish netting is sometimes used, but it is too hard for the tender skins of the Peach and Nectarine, and is very apt to bruise them. The safest plan is to use frigidome. Lengths used on walls for protecting the blossom of fruit trees answer capitally, and if these are arranged so as to form a double receptacle for the falling fruit, one about half way down the tree and the other near the base, the fruits have only a short distance to fall and are got at easily. A layer of soft hay should be laid in front of dwarf trained trees to catch the fruits which do not fall through the trellis on to the frigidome.—B. S. N.

Night air for Vines.—An experienced Grape grower and successful exhibitor recently expressed an opinion on night air for vineries. The practice, he maintained, was unnecessary and extravagant. He had abandoned it for the past three years, and with closed ventilators his Grapes had coloured beautifully. What first convinced him that night air was unnecessary was having a vine in which Gros Colman, Black Alicante

and Gros Maroc were growing. The ventilators had to be kept closed during the night in order to keep up a sufficiently high temperature for the Colman. Yet the two other varieties finished perfectly. Referring to the fine Hamburgs our forefathers grew and ripened in the hottest part of the summer, he said they were obliged to give night air to keep the figure down to 65°, Hamburgs not finishing satisfactorily in a higher one. He admitted that during the extremely hot weather of last August the ventilators had to be left open at night, but in ordinary weather they are closed, conserving fire-heat, the pipes being made lukewarm. It is the practice of admitting air on cold nights and then having to burn fuel to make up the deficiency in heat, that he specially condemns. I confess I never had much faith in the night air system, and the best coloured bunches of Lady Downe's I ever saw were in a vinery which was quite closed every night.—J. C.

Melons.—There has been a comparative paucity of new Melons this year, happily. Probably raisers are beginning to find out that with new varieties they make no advance, for in the matter of flavour, flesh, appearance, freedom, and all other ordinary attributes we are still about where we were in Melons ten or more years ago. When writers on Melons recommend varieties, we hear very much more of old standard ones than of new ones; indeed, so many of the new ones are after all when grown for comparison so much reproductions of old ones. It is very interesting to look through a house in which some twenty to twenty-five assumed varieties, old and new, are growing for trial, and thus note how similar are old and new. A remarkable tribute to the enduring merits of a fine variety thirty years raised, William Tillery, was paid the other day when the raiser, Mr. J. Miller, exhibited it in several fine fruits in first-class condition, and for the time of the year capitally flavoured. We have others, but none green-fleshed that are better. Would that in future years Melon growers when they intercross and produce a variety of seedlings would first grow and select stocks for three or four years before submitting to the fruit committee, and also see how far or how little the seedlings differed from older ones. Only recently when a seedling variety was submitted for approval it was found the flesh of two fruits was of diverse colours.—A. D.

Galvanised wire.—There is no doubt that galvanised wire has been answerable for a lot of wounds on the shoots of fruit trees, both inside and out, and Mr. Hudson has done well to call attention to the same. The remedy, however, if the wire cannot be removed, is not far to seek: simply a twist round the wire and a half knot with any tying material that is employed, and then to tie the shoot so that, in fact, it is simply enveloped in the tying material and does not in any way come into contact with the wire. There may be something in the hot-and-cold-current theory, but it must be remembered that anything in the way of iron (nails, for instance, either cast or wrought) has the same effect where it is pressing on the young bark. So far as the appended note is concerned, I am quite in accord with the Editor for Oak or Chestnut trellising for strong-growing climbing plants, but fail to realise its application for the majority of fruit trees such, for instance, as the Peach, Nectarine, and Morello Cherry. All things considered, however, I do not think any better plan can be found than to fasten the trees to the wall, especially where facilities exist for an annual winter unnauling, and giving the wall a thorough good dressing with some mixture that shall contain sufficient insecticide to kill insects, and be thick enough to stop up the majority of nail holes. Where insects are troublesome it is advisable to dispense with cloth shreds and to use fine tar twine and medicated shreds as fasteners, respectively for old and young wood. For such things as Raspberries, Gooseberries, and Currants, when grown on trellis work I do not see the necessity for dispensing with galvanised wire if twisting the twine preparatory to tying practised, and so far as the two latter

fruits are concerned, this twisting is only necessary with young wood. I have Gooseberries on galvanised wire that have been in their present positions nearly seventeen years, and they are healthy and vigorous, producing annually good crops of fruit.—E. BURRELL.

GOOSEBERRY HEDGES.

I CAN corroborate what Mr. Fish says about Gooseberry trees making good and profitable hedges. I know a village a few miles from Cromer in which some of the cottagers' gardens are divided by hedges formed of Gooseberry trees. These for many years produced abundance of fruit, the varieties being principally smooth and hairy-skinned yellows. The only objection to this mode of planting is that growth is liable to become so dense as to render picking the fruit difficult. I know of one garden where Gooseberries are grown of fine size and quality on wire fences, and this mode of culture might be adopted in many instances where newly-planted orchards or fruit plantations are fenced round. Horizontal wires are the cheapest, these being about a foot apart, wire rabbit-proof netting—the widest procurable—being fixed along the bottom and the Gooseberry trees trained thereto. A border 2½ feet or 3 feet in width and consisting of good holding loam and decayed manure should be prepared. Fan-shaped trees are best, and these are procurable at any good nursery. The branches may be laid in 3 inches or 4 inches apart and the close-spur system of pruning practised. The border should be well mulched with short manure early in spring, and never allowed to become infested with weeds. In dry summers it will be necessary to give several good waterings, and established trees carrying full crops of fruit will be benefited by heavy applications of farmyard liquid. Trees so grown are not so liable to be attacked by bud-eating birds in winter, or fruit-devouring ones in summer as ordinary bushes, which screen them from view. Insecticides can also easily be applied to save the foliage from injury from red spider and caterpillars. With abundance of sun-heat and fresh air, such varieties as Whitesmith and Warrington attain to the highest perfection, while the larger exhibition sorts, if liberally fed while swelling, reach a size unobtainable under any other system of culture. While Gooseberries exposed to a maximum of sun-heat are, of course, the best flavoured, the cultivator need not hesitate to plant on fences or form hedges in shady positions, as trees so situated bear freely. J. CRAWFORD.

Apple Beauty of Stoke.—In appearance this somewhat resembles the French Crab, but the fruit is more even in outline and conical in shape. The colour is a deep green, covered with small russet dots on the shaded side, with a flush of red on that exposed to the sun. With me this season the trees have been most prolific, fruit sound, and of first-class quality. As a medium-sized exhibition variety it should stand well, as the flesh is firm and keeps in good condition till late in the season.—H. C. P.

Pear Comte de Lamy.—One would have thought, considering how much good flavour is appreciated now-a-days, that there would have been a stronger competition in the class for this delicious Pear at the Palace show. Probably its size tells against it, but even in this respect it is far more suitable for ordinary dessert than the extra large varieties. Comte de Lamy is a favourite Pear in East Anglia, and I remember a note in its praise from Mr. Temple, of Carron House, but whether he spoke of its merits from the fruit he saw in Suffolk while living there a good many years ago, or whether it succeeds in his present locality, I am unable to say. Perhaps Mr. Temple will kindly say.—J. CRAWFORD.

Mildew on Vines.—Those who are troubled with mildew on their Vines will be glad to hear of a simple and effectual remedy. It was made

known to me by a Grape grower residing on the east coast where the malady is often troublesome through the rapid changes of the wind producing a chill. Previous to pruning, the house is closed, and any plants removed from the range to other quarters. Four ounces of sulphur are then placed on hot coals, this being sufficient for a vinery 30 feet in length. The grower in question has practised it for years, and his Vines have been free from mildew, whereas formerly they suffered much from its ravages. He assured me that this simple remedy does away with the need of sulphide of potassium or any other application the next season.—NORWICH.

Pear Thompson's.—"Hortus" does well to bring the merits of this delicious Pear before the readers of THE GARDEN. Considering its high quality, it is a wonder it is not more frequently met with. Only some six or eight dishes of it were exhibited at the Palace show, these being of no special merit as regards size. Probably the hot, dry autumn is responsible for the small size of the fruit, as no Pear that I am acquainted with changes from a green to a golden colour so suddenly in extra hot seasons. Thompson's is by no means a handsome-looking Pear, the shape being irregular, but its good qualities compensate for this. I think it is quite as highly flavoured as Doyenné du Comice, though perhaps not so prolific. It must not be planted in cold, retentive soils, or small, cracked fruit may be expected.—C.

Strawberry Bicton White Pine.—This Strawberry is not often met with, neither is it often mentioned in the reports of fruit crops. All the same it has considerable merit, and would be appreciated in many gardens if once seen and tasted. It requires good cultivation and then crops well, the fruit being similar in size to well-grown samples of Sir Joseph Paxton. I have known it do well in Kent in a heavy loam, and in one private garden where I was employed it was the owner's favourite Strawberry. Although its colour would probably tell against it as a market variety, it has a very handsome appearance when dished up for dessert. It is always best to give the plants plenty of room, so as to allow of a free circulation of air amongst the plants, as the fruit soon suffers from wet or damp.—NORWICH.

Strawberries Empress of India and Grove End.—Empress of India is one of the best, if not the best, flavoured of all Strawberries. It is not one of the strongest growers, and to get the best results special culture is needed. The best plan is to plant out healthy young layered plants in autumn, and the following spring select some half-dozen of the strongest runners and peg them in at equal distances apart around the parent plant; next year a capital crop of fruit may be expected. The most suitable soil is a good holding loam. A noted fruit grower has pronounced Empress of India of richer flavour than British Queen. This is saying a good deal, but there cannot be any doubt but that it is an excellent Strawberry. Some gardeners still prefer the old small-fruited variety Grove End for preserving, the colour being good. The above method of culture also suits this variety, as it is of rather weakly growth, though abundantly prolific. It is also known by the names of Carolina and Old Scarlet Pine.—C.

Grape Golden Queen.—Reference has often been made to the muddy appearance this Grape takes on just when on the point of ripening. What a pity it has this drawback, which entirely spoils it for market, as, so far as cropping—which is equal to that of the Black Hamburgh—and flavour are concerned, no fault can be found with it. Could but this colour defect be overcome, market growers might plant whole houses of it. One occasionally meets with brightly-coloured examples, the best in this respect I have ever seen having been in a long span roofed vinery at Sundridge Park. The Vine received abundance of light, sunshine, and fresh air. It was stated by a correspondent some time ago that shading the bunches after colouring commenced would

prevent discoloration of the berries. I have tried this, however, but with no good result. Muddy bunches are also apt to shrivel suddenly later on. Golden Queen has been kept in a plump condition at Chilwell Nurseries, where it was raised, until late in spring.—J. C.

Watering fruit trees.—Various causes have been assigned as to the shortness of fruit this season, but one that I feel confident has a lot to do with it is seldom mentioned. This is the dry, or generally dry, autumn of last year. I have no doubt in my own mind that a dry autumn up to the time the leaf begins to fall is not beneficial, and unless we get heavy rains between the middle of August and the middle of November, trees have not the same chance to finish up the wood properly and develop plenty of good fruit-buds. The buds may be there, but they are not strong enough to ensure fertilisation and a swelling of the fruit. For this reason watering is of the utmost importance, and especially is this necessary when trees are transplanted. The present year has been very dry so far, and trees received from the nurseries have in some cases been quite shrivelled on arrival. All of these—every tree received in fact—have been thoroughly soaked at the roots before untying the bundles by standing them in open tanks and barrels. After planting, each tree has received a thorough soaking, this consolidating the soil, and the growths have plumped up capitably.—H.

Apples which fruit on the points of their shoots.—A good many Apples bear their fruit principally on the points of the shoots, and are, therefore, not suitable for growing as espaliers, pyramids, or cordons. Most of these terminal fruiting varieties are, nevertheless, grown and sold in espalier form, and often prove a source of annoyance by their continued barrenness year after year. One of the most prominent of this class is Irish Peach. I have planted it in espalier form, and owing to its free growth have been able, by rigorously thinning out the growths in summer and leaving the most promising equally distributed all over the tree, these being finally regulated and tied to the wires in winter something after the style of a Peach tree, to secure a lot of good, highly coloured fruit, but for all that the tree never looked well on wires. To spur it in the ordinary way is to court failure. Golden Noble is another Apple which should be avoided in espalier form, though a very prolific variety as a standard or bush. Lady Sudeley is described as a terminal-bearing Apple, which it is if grown in standard or bush form, but, being an exception to the rule, it forms abundance of spurs and fruits freely in cordon form. I fancy The Queen belongs to this section, as I have never induced it to bear as an espalier.—C.

Too many varieties of Apples.—When but recently Mr. G. Bunyard staged at the Westminster Drill Hall 100 assumed distinct varieties of dessert Apples, it was well said that a reduction of that number to twenty varieties only would be a great boon. That the collection included all the leading varieties in cultivation there was no doubt, but nothing would have been lost, and much gained, had the exhibitor kept fifty of the varieties, notably inferior to others, at home and sent but fifty of the best. The work of making a good selection of the very best twenty would then have been much easier. I have thought that some useful purpose might be served by first publishing the names of Mr. Bunyard's 100 varieties, and then inviting a census of opinion from readers as to the best twenty from the entire number. But some of the earliest ripening varieties would still be excluded, which, however, would be of little consequence, as they have very fleeting existences. The selection should be one specially suited to provide a supply for the table from October 1 to March 31. Of course, even with such selection almost unanimously made, nurserymen would still go on growing and cataloguing the inferior varieties, but the publication of the list in the pages of THE GARDEN might help to educate the public so far that infe-

rior varieties be not asked for, and they would then in time die out. Our home-Apple trade suffers severely because of the myriads of worthless Apples we grow so largely all over the kingdom. Really valuable varieties come slowly. None should be included in the list that have not been well tested for at least ten years.—A. D.

DESTROYERS.

THE PEAR MIDGE.

(DIPLOPSIS PYRIVORA (RILEY); CECIDOMYIA NIGRA (NEIGEN).)

THE Pear midge, according to a leaflet just issued by the Board of Agriculture, sometimes causes serious losses in orchards by its attacks on Pear trees. Some Pear growers seeing the young Pears falling fast in June, when they are about the size of marbles, think that this dropping is due to an unhealthy condition of the tree or to influences of the weather, but it is more often due to the insidious and dangerous action of the tiny Pear midge, the presence of which is far more common than is usually believed.

It would appear that early Pears, and those that blossom early, are most likely to infestation by this insect. Williams' Bon Chrétien is notoriously subject to it, and in America, where the Pear midge is very prevalent and most destructive, the Bartlett Pear (identical with Williams' Bon Chrétien) and the Lawrence are the varieties chiefly attacked. Beurré de l'Assomption is also frequently seriously affected. Pitmaston Duchess, Marie Louise, Jargonelle, Souvenir du Congrès, all early, and like the Bon Chrétien in many respects, are also especially liable to be infested. Infestation has been noticed on later Pears, as Josephine de Malines and Catillac, but in a much less degree than on earlier varieties. Professor Riley, writing in 1885, considered that the insect had been imported from Europe, as until it was found in 1880, upon a certain farm near Meriden, in Connecticut, no insect of similar habits was found in the United States.

It is not known how long the Pear midge has been at work in this country. It was first mentioned twenty-five years ago, and there is every reason to believe that it had been present here long before this, for its action upon Pears, as pointed out above, closely resembles that of weather and other natural causes, and might easily have been mistaken for these, especially as there were then comparatively few trained observers.

LIFE-HISTORY.—The fly is nearly one-tenth of an inch long, with an expanse of wings equal to close upon one-fifth of an inch. Its slender body is dark grey, approaching black, in colour; its antennæ are brown and very long; its legs are also very long and yellowish brown. The female is slightly longer than the male. The number of eggs, according to Schmidberger, varies from a few to more than twenty. They are hatched in a very short time if the weather is warm. Small larvae, which begin to bore into the blossom usually in or near the stem of the calyx, were found by Schmidberger on the fourth day after the deposition of the eggs. "Before the blossom is expanded they descend to the core, so that they may not be exposed to the sun's rays, which would endanger their existence. They separate at the core and begin to devour it on all sides. When they have consumed the pulp of the small fruit they have attained their full size, and only await a favourable opportunity to leave their still secure dwelling." Sometimes they fall from the Pears to the ground; sometimes they fall

with the infested Pears, from which they emerge and bury themselves in the earth to a depth not exceeding 1 inch. The larva is endowed with powers of jumping like other species of Diplosis. It can also crawl well, but it has no legs. It is rather more than a twelfth of an inch long. In colour it is whitish yellow, becoming rather darker as it gets older. It has what is known as the "anchor process" or "breast bone," which serves as an adjunct to the mouth in biting pulp and tissues, "broadly dilated," as remarked by Professor Riley. This is light brown in colour, bifurcate in shape, and is easily seen with an inch lens. It is not known when the pupal state is assumed. It has been ascertained that the larvae remain for some time in larval condition before commencing their cocoons, and that they remain, according to Riley, in the cocoons for some time before being transformed to pupæ. The pupa is about one-tenth of an inch long, black above and yellowish brown beneath.

PREVENTION AND REMEDIES.—It is absolutely certain that the author of this mischief to the Pear crop is lying just under the Pear trees from June until the end of March, and only about an inch below the surface of the ground. It may therefore be assumed that thoroughly digging the ground beneath the boughs of the Pear tree, making allowance for the skipping or jumping habits of the larvæ as they come from the Pears, will bury the larvæ so that the flies cannot emerge. This should be done as a means of prevention where possible. It would be necessary to dig the ground with digging "spuds" so as to completely turn it over, and the action of winter rains and frosts would pulverise it and make it compact, and thus prevent the flies getting through the clods. Obviously this could not be done in grass orchards. Dr. J. B. Smith, who has closely investigated this subject, says "ploughing an orchard" (and ploughing is a frequent mode of cultivating orchards in America) "infested by the midge, after the middle of June, or, in fact, at any time during the summer, so as to turn the soil at least 4 inches, will probably result in burying beyond resurrection a great proportion of the midges." Ploughing is not carried out in England, but many orchards are dug, and in gardens it would be easy to adopt this practice. Dr. Smith, who has made careful experiments in connection with the Pear midge, has also found that dressings of kainit immediately under infested trees have been most effectual in killing the larvæ. He recommends that the ground under the trees should be top-dressed with one ton of kainit per acre, and mentions an instance of an orchard thus treated, of which the fruit practically escaped infestation, while in an adjoining orchard not treated he failed to find a single fruit that was not infested with larvæ. This treatment has been successfully adopted by several Pear growers. The kainit should be put on between the middle and end of June, before or immediately after rain. It is also suggested that ploughing or digging might advantageously follow towards the end of July or in August. Where Pear trees are in grass orchards the grass should be cut very close before the kainit is put on. It is desirable to apply the kainit before the larvæ get into cocoons, as it has much more effect upon them in their naked state. Rain, or the moisture of the atmosphere, causes the kainit to dissolve slowly, and the caustic solution thus formed burns the tender bodies of the larvæ that are within its influence.

With respect to actual remedies, it must be said that they are few and not satisfactory.

Spraying with insecticides is of no avail. Spraying with offensive materials, as paraffin or carbolic acid, might prevent egg-laying if done just at the right moment. Dr. Lintner suggests sacrificing the Lawrence Pear crop by spraying Lawrence trees with London purple just after the fruit is formed in order to kill midges and starve the larvae within the Pears. But, unfortunately, other Pear trees are liable to infestation, and in England it would be more difficult to select the trees most subject to this attack for this purpose. Picking off and burning infested fruit can be adopted in the case of small bush, espalier, wall trees, and half standards, but it could not be done on standards. As a rule infested Pears can be recognised by their malformation, so that it would be easy, after the pickers were instructed, to pick them off and leave the sound Pears.

STOVE AND GREENHOUSE.

WATERING PLANTS.

ONE of the most important factors in the successful culture of plants in pots is the judicious use of the watering-pot. It would be difficult to lay down any definite laws on the subject, and still more so to find young men who would carry them out. Watering has to be regulated to a great extent by local circumstances, also by the requirements of the different plants under treatment. It would be quite safe to say that more err in over-watering than in not giving enough. This is particularly the case in regard to Fern culture. It is a common idea that all a Fern requires is to be potted in peat, heavily shaded, and drenched with water, but many of our most tender Ferns may be grown fully exposed to the sun, potted in loam, and kept rather dry than otherwise. It is after re-potting that they are most liable to suffer from too much moisture. If the new soil gets soddened before the roots have taken hold of it they will never make a good start, but after the pots are well filled with roots they will take more water, yet either extreme should be avoided even then. With all flowering plants the evil of over-watering is equally apparent. Various subjects, of course, require different treatment, and just at the time they are in full bloom they take up much more water than previously without regard to the pots being fuller of roots than at the earlier period, and many fail to flower satisfactorily if only once allowed to get too dry after the buds are set. I have often heard the cause of Camellia buds dropping being disputed. I believe there are more lost through drought than any other cause, though keeping the house too warm for a few days and then lowering the temperature again will prove equally disastrous. Mignonette is, perhaps, one of the subjects that require the greatest care in watering. I remember once having a splendid batch just coming into flower, and having to be from home, I found on my return that it had been quite withered down, but had just been watered over twice; the result was that it was completely spoiled, the drought having crippled the tender roots, which prevented them taking up the water when it was given. If only a light watering and sprinkling overhead had been given it might have revived, but the over-watering, with roots not in a condition to take it up, was fatal.

Poinsettias and Euphorbia jaequinia-flora are both very liable to lose their roots through either extreme. The result is more frequently seen when the soil is too wet. Yet at the same time it may have been caused through being too

dry in the first place. During the winter, plants standing on a moist bottom will require comparatively little water, while those on a dry stage, especially if there are hot-water pipes beneath, are liable to dry at the bottom while the surface may appear moist; this is more likely to happen where the syringe is used. Speaking of the syringe, it is a splendid instrument when judiciously used, though much mischief often occurs through using it at the wrong time and by not handling it properly. I prefer a syringe with a jet nozzle, and to regulate the force with the finger. With a little practice it is easy to produce the finest spray or give more force as desired, and it can be directed under the foliage better than by a rose nozzle. Red spider would not prove so troublesome if more regard were paid to thoroughly wetting the under side of the foliage of plants subject to this pest.

For syringing, I prefer to have the water as near the temperature of the house as possible, though this is not absolutely necessary, for I have had to use quite cold water for stove plants, and have been unable to detect any evil results. I fully believe it is better to use water below than above the temperature of the house, and for watering I have found that warm water would do harm, but have never proved that cold water was detrimental, though I have never gone to any extreme.

Some years ago I had a discussion with the late Mr. Bause (who was one of the cleverest propagators of his time) on the subject of watering cuttings with cold *versus* hot or warm water, and he was much in favour of cold, and I have followed his advice, and I may add with good results. SUSSEX.

Pentas carnea.—So continuous blooming is this, that with a few plants I have not been without flowers for months, and, favourably situated, they will continue to bloom well on into the new year. The little clusters of blush-tinted blossoms cannot at any time be regarded as showy, yet they are very neat and pretty, and are very useful in a cut state. Where needed only for late autumn and winter blooming, the cuttings should be struck early in the spring and grown on freely during the summer, being stopped occasionally in order to induce a bushy habit of growth. The flowers, too, should be pinched off till required. A form of this usually regarded as a distinct species under the name of *Pentas kermesina* has rather smaller blossoms of a bright carmine-rose tint. It affords a very pleasing variety to the better-known kind, but it is of a weaker constitution and needs more care in its culture. At one time it was freely met with, but of late it appears to have become somewhat scarce.—P. H.

Epiphyllum truncatum Princess.—This extremely pretty form of *Epiphyllum truncatum*, which received a first-class certificate at the Royal Horticultural Society's meeting on November 22, is, apart from its own intrinsic beauty, of considerable interest from the fact that, despite the popularity of the *Epiphyllums* some years ago, only one variety of *E. truncatum* has been previously certificated, and that was as long ago as November 8, 1864. The new form, *Princess*, is much lighter in colour than the majority of those which we have in cultivation. The flower is white, suffused with purple, which colour is deeper towards the centre than at the edges, while in the throat there is a ring of purple-lake, the long protruding stigma being also tipped with the same colour. Judging by the specimens exhibited, the flowers appear to deepen somewhat in tint with age, as the freshly-expanded blooms were paler in hue than the older ones. *Epiphyllums* of this class are as a rule grafted standard high on the *Pereskia*, with which they readily unite, but such is by no means absolutely necessary for their increase, as cuttings strike readily, and

when they are grown in suspended baskets this is the best way of propagating them. As bushy plants in pots they are, owing to their pendulous nature, seen to better advantage when grown as standards. The plants shown were grafted on to thick, fleshy stems, probably some kind of *Cercus*.—H. P.

Bouvardia leiantha.—For size of flower this species cannot compare with many of the popular kinds, but it is a useful and pretty plant that is deserving of attention where a quantity of cut flowers is needed. The pretty little corymbs of scarlet blossoms are especially bright and telling just now, and its colour is quite distinct from that of any other. It is easily grown into neat bushes by keeping the plants sturdy in the early stages and pinching frequently. It is very free flowering; so much so, that occasionally it is necessary to pinch out the blooms as soon as they show, or but little growth would be made. Cuttings taken in early spring make nice little plants the first season, but they are better the second, and if arranged alongside one of the long-tubed white varieties, as *B. jasminoides* or *B. Humboldtii corymbiflora*, it has a fine effect in the conservatory or greenhouse. A frequent mistake in *Bouvardia* culture is coddling the plants, especially in the earlier stages, this leading to weak, attenuated growth that is not likely to flower freely, if at all. If grown in pots, *B. leiantha* must be stood in a frame or plant protector during the summer and syringed freely morning and evening. This serves to keep down green-fly, this insect being especially attentive to *Bouvardias*, or the plants may be placed in frames in a peaty compost, made quite firm, and lifted and potted in autumn for flowering.

COSTUS IGNEUS.

ONE of the brightest features just now in the stoves at Kew is this *Costus*, referred to in a recent issue, which is so attractive that its comparative scarceness is not at all easy to account for. It is one of the numerous family of Gingerworts, many of which are remarkable for their showy blossoms, though in some cases they do not last long. This species is no exception to the rule, but as a set-off a succession is kept up for a considerable time; indeed, so free-flowering is it, that a few well-established specimens will bloom more or less continuously throughout the year. *Costus igneus* forms a dense leafy clump, while the blossoms are borne in cone-like heads on the points of the shoots. They are a couple of inches, or nearly so, in diameter and of an intense deep orange colour. Though the flowers are thin in texture and do not last long, several are pushed out from the same head. This species is a native of Bahia, and was introduced by M. Linden in 1852. Its cultural requirements are not at all exacting, as it can be readily grown in pots in the stove, while if planted out it is, as a rule, even more satisfactory. The specimen referred to at Kew is planted at one end of the new *Nepenthes* house, and its numerous brilliantly-tinted blossoms were particularly striking on a dull November day. It furnished a good illustration of the now generally recognised fact that yellow flowers are more conspicuous during extremely dull weather than those of any other tint. This *Costus*, like the rest of its race, can be readily increased by division, which is best carried out in the spring. There are several other species, but this is the most brilliantly-tinted of any that I am acquainted with. A second kind, *C. speciosus*, was illustrated by means of a coloured plate in THE GARDEN, March 9, 1895. In this the delicate white blossoms are pushed out from a peculiar red cone-like arrangement with which the principal shoots are terminated. This is altogether a stronger-growing plant than the preceding, reaching as it does a height of 4 feet to 5 feet. It is a native of India, and occurs plentifully in some districts in disused watercourses and such spots. Though uncommon here, it was introduced as long ago as 1799. T.

FERNs.

THE BLADDER FERNS.

(CYSTOPTERIS.)

With the exception of the North American *Cystopteris bulbifera*, all Bladder Ferns, so named in allusion to the nature of the covering of each spore mass being inflated like a bladder, may reasonably be considered as British plants, although most of them also exist in a wild state in various mountainous parts of Europe. Indeed, they are found to inhabit the temperate zone of both hemispheres. The genus only contains four species, viz.: *C. alpina*, a very pretty Fern seldom exceeding 8 inches in height; *C. bulbifera*, the fronds of which usually measure from 12 inches to 18 inches in length, but are occasionally longer; *C. fragilis* and its several varieties, viz., *angustata*, with fronds 15 inches long, *dentata* and *Dickieana*, which seldom grow more than 5 inches high, and several other intermediate forms; and last, but certainly not least, the very beautiful *C. montana*. An idea of the elegance and graceful habit of this species may be readily formed from the illustration by those who are not acquainted with the plant.

It is, indeed, the privilege of but very few Fern lovers to see, and of a still more restricted number to possess, *C. montana* in all its glory, for it bears the reputation of being a bad, or at least a very capricious grower. For many years its culture has been considered very difficult, but when one sees such specimens as the one here reproduced from a photograph taken and kindly lent by its grower, one feels anxious to be favoured with the mode of growing which produces such wonderful results. This is as simple as it is effective, and we owe the history of the discovery of the new treatment to the kindness of Mr. O. Firth, of Baildon, Yorkshire. This gentleman, who is a very keen observer and who has had remarkable success with this plant, adopted the culture which, to him, appeared the most rational after a careful examination of the rhizomes and of the roots of his plants, which previously would grow no better with him than with other growers. Mr. Firth, having found that his plants, although producing no top growth worth mentioning and gradually dwindling away, had a peculiar way of extending their tiny rhizomes until they reached the drainage of the pans, when they became more substantial, hit upon the idea of excavating a pit and filling it to the depth of 12 inches with coarse and small brick rubble and only a very little loam and leaf-mould, into which the rhizomes were planted and buried over. This was in the month of October, when one good substantial watering was given to settle the compost, and no more attention was paid to the new plantation. The following year the plants surprised their owner by their improved condition, and the following season, and without anything further than ordinary watering having been done to them, they astonished all who had the good fortune to see them. I have now in my possession a frond measuring 18 inches high and 10 inches across at the base of its leafy portion, and this is by no means an exception, as those lovely fronds of a beautiful light green colour are produced in great abundance and from rhizomes which are fully the size of an ordinary lead pencil.

All other known *Cystopteris*es produce their fronds from a tufted crown, and are propagated by the division of the crowns or from spores sown in autumn in a cold frame. *C. bulbifera*, however, is more readily increased by means of

the little bulbils, which are abundantly produced, and which are usually found on the under side of the fronds, mostly at the base of the leaflets. These singular growths consist of two, sometimes three, and even four rounded, fleshy, cotyledon-like greenish or deep-coloured masses containing a rudimentary frond or two between their bases. Having fallen to the ground, they soon emit a few slender roots and produce perfectly developed plants during the second year. *C. montana* is the only known species provided with running rhizomes, a character which renders its propagation easy when the plants grow freely, as they do with Mr. O. Firth at Baildon. Its discovery in Great Britain is of comparatively recent date, for although it had long been known as a Fern peculiar to the high alpine districts of Europe—the Jura and Dauphiné Mountains, the Swiss and Austrian Alps, and the Pyrenees—it was only in 1836 that Mr. W. Wilson found it on Ben Lawers. So interesting is the history of the Mountain Bladder Fern, that the observations made by the late Thomas Moore are well worthy of being reproduced here—

The headquarters in Britain of this very rare and local Fern are the Highlands of Scotland, where it grows on mica schist, and where it was first found on Ben Lawers by Mr. W. Wilson, in

Cystopteris montana. From a photograph sent by Mr. O. Firth, Hawthorne House, Baildon, Yorks.

company with Professors Hooker and Graham, in 1836, and subsequently by Messrs. Gourlie, Adanson, Borrer, and Little, and Dr. Walter Arnott, in 1841, 1850, and 1851, in a ravine called Corrach Dh'Uaillach, or Corrach Uaehdar, between Glen Dochart and Glen Lochay, in the Mhiel Uaillach Mountains, in Perthshire. It is reported to have also been found in North Wales by Plukenet, and we are informed that the existence of the species in Wales has been recently confirmed, though the information is incomplete. It is not, however, improbable, as the species is met with in the Alps of Europe, occurring most frequently in the north, and generally on rough, stony ground. This is strictly an alpine plant, and requires treatment similar to that recommended for other species, with perfect rest in winter.

Eaton, in his splendid work, "Ferns of North America," says that it is one of the rarest of North American Ferns, and states that it is found growing by the side of streams in shady alpine woods in the Rocky Mountains of British America and on the north shore of Lake Superior, and it may be added that it is generally in similar situations that it is also found in Central Europe. S. G.

ORCHIDS.

MORMODES.

It is difficult to say why these Orchids are not more popular, for they are extremely interesting and beautiful, never failing to flower if properly grown, while their requirements call for no very special skill. It is true that a certain amount of care is needed, especially early in the season when the young growths are starting, and an over-dose of moisture is apt to lead to mischief, but this may be said with equal truth of many other popular kinds. The plants are closely allied to *Catasetum*, and they resemble each other in the quaint forms of the flowers and the manner of fertilisation. They are mostly deciduous, having scaly pseudo-bulbs and deep green foliage of rather a thin, yet tough texture. The best place to grow them is in the warmest part of the Cattleya house, where they will have abundance of light the year through, or they may, if more convenient, be placed in the warmest house while growth is active, and removed later when it is finished to a cooler and drier position. In a collection of these plants there will be some individual specimens that carry their foliage much later than others, and

it is better not to try and bring them in a line, as they flower over a longer season. The first part of the season, as noted above, is when the plants need most care in watering, and the less they get the better, for stored up in the large fleshy pseudo-bulb is ample nutriment for the young growths. Again, a little later when the top of the growth forms a cup-like cavity that will hold water, all overhead watering should be given up and the atmosphere kept moist by other means. Although the foliage of these Orchids is of a kind that likes ample sunlight,

it will be found to scorch easily if at all wet from night moisture when the sun reaches it. This makes early morning ventilation necessary, and not only this, the air so provided helps to harden and ripen the pseudo-bulbs. As the season goes on the foliage hardens and will stand almost direct sunshine, and soon after the top leaf has attained its full size and the pseudo-bulb has done swelling, the water supply must again be diminished by degrees, as the foliage loses colour and falls. Those plants having flower-spikes in course of formation need a little more moisture than others. The size of pot or basket used for the plants will depend on the habit of the species to some extent. The luxatum and pardinum varieties, being of average size, may have about a couple of inches margin all round the plant, with less or more according as the species is strong or weak. Many growers use baskets for them, and very pretty the arching flower-spikes look when suspended.

A fair percentage of sound fibrous loam is an excellent addition to the compost for these

plants, and the peat and Moss should also be of the best quality. Repotting or rebasketing is best carried out in early spring, and if a little top-dressing is allowed in the intervening seasons, once in two or three years is often enough. The leaves of *Mormodes* are very liable to be attacked by red spider, thrips and other insects, the old leaf bases that cling round the pseudo-bulbs after the foliage has fallen making comfortable winter quarters for them, whence they issue to the young leaves and soon spoil their appearance. The sheaths must not be removed, but a good deal may be done by careful and continuous cleaning and sponging, besides keeping the atmosphere of the house genial and moist.

MORMODES BUCCINATOR is one of the handsomest and most remarkable in the genus, a very variable plant as regards colour, some varieties being extremely bright and showy, others poor. What is usually regarded as the type has yellowish green sepals and petals, with a white lip; in others this ground is very beautifully mottled and spotted with various shades of rose and purple. The habit is not so large as in some, the spikes are erect and usually produced in late summer and autumn. It has been in cultivation since 1840.

M. CARTONI was introduced soon after the above-mentioned kind, having been sent to Kew by Mr. C. Purdie in 1842. It closely resembles some of the forms of *M. Buccinator*, and forms of it have been recently exhibited under the latter name. The pseudo-bulbs are longer, as is the foliage, and the flowers are much smaller than those of the above. The sepals and petals are yellowish, spotted variously with red and purple. It first flowered at Syon House a few years after its introduction.

M. COLOSSUS is a large growing handsome species, reaching a height of about 2 feet and bearing large, striking, though not pretty flowers, each about 5 inches across. The sepals are yellowish, tinted brick-red at the base, and the thick column a deep green. In my notes on this species made some years ago I have it as a very strongly-scented Orchid, but I have not seen either plant or flower for a long time. It comes from Central America and was one of the discoveries of the Polish collector Warszewicz.

M. LUNATUM is not itself particularly handsome, though the yellowish tint is somewhat unusual, but its variety *eburneum* is one of the very best of all. Its flowers are pure white, with the exception of a slight tinge of brownish red upon the lip. Another variety has prettily spotted flowers and the ground varying from pure white to pale yellow. It is a native of Mexico and was discovered by a collector in the employ of Mr. G. Barker, of Birmingham, in 1839.

M. OCANE is an old species, discovered many years ago by Schlim near Ocana, and probably not introduced alive. In 1879 it flowered with Messrs. Veitch and Sons, the plants having been sent home by their collectors. The colour of the flower is yellow, but so closely covered with reddish brown spots as to almost appear wholly of that colour.

M. PARDINUM is one of the best known and a fine Orchid, flowering freely at almost any time of the year. The spikes are prettily arched and thickly set with golden yellow flowers, these being spotted with reddish brown or chocolate. The variety *unicolor* is of a soft pale yellow, without spots of any kind. The plant was introduced in 1837, and it flowered soon after with Mr. Bateman, of Knyppersley. It has been frequently imported since and is a native of Mexico. Many other kinds more or less distinct have been named at one time and another, including the deep claret-coloured *M. omanthum*, exhibited by Sir Trevor Lawrence at the Drill Hall last April, but some, such as *M. igneum* and *M. uncia*, are doubtfully distinct, while others are very rare if not now misrepresented in collections.

Cypripedium Niobe.—This is a very lovely little hybrid, raised in the first place by Mr.

Seden, and since then in a few other collections. It is about 3 inches across; the dorsal sepal is white flushed with rose, and has a bright green patch at the base like *C. Spicerianum*, one of its parents. Its other parent is *C. Fairieianum*, and, like the majority of hybrids raised from this rare kind, it has the same pretty drooping and recurving petals. The colour is a soft, yet bright green overlaid with chestnut and brown markings, the green, rose and brown lip making up a truly beautiful flower.

Sobralia macrantha alba.—This has turned up in several collections recently, and a lovely flower it is. Its correct name is *S. m. Kienastiana*, but *alba* is simpler and is more often used. Compared with the type it is not nearly so tall, but flowers with the same freedom if properly grown. Doubtless these plants are in some cases overdone with compost and water, but much oftener they are half starved from want of room in the pots, and need material for the large fleshy roots. A fair proportion of good sound loam should be mixed with peat and chopped Moss for these plants, and the pots should be fairly large and well drained.

Phalænopsis Lowi.—One of the prettiest of the dwarf *Moth* Orchids, this is also one of the worst to grow. Its native habitat is in Moulmein, where it loses its leaves after flowering and rests entirely for a few months. If under cultivation it were safe to dry the plants sufficiently to give them this thorough rest, and at the same time to prevent loss of energy, they would doubtless be more generally satisfactory, but in many instances the resting season is when they go wrong. Plants that produced nice stout little leaves one year gradually dwindle away and become too weak to flower, and, owing to this, many growers are in the habit of only partially resting it. The plants vary a good deal, for in some instances it would seem impossible to prevent the loss of foliage, and such are, perhaps, the most generally satisfactory. Give just enough moisture about them in winter to keep the roots plump, and in spring, when the foliage appears, grow them as strongly and rapidly as possible. In no case is much compost necessary, a little Moss about a block or basket being all that is required. The flowers occur on semi erect spikes about a foot high, and are each a couple of inches across, rosy white, with a suffusion of rich purple about the base of the petals and the lip. It was introduced by Messrs. Hugh Low and Co. in 1862, having been discovered and sent home by the late Rev. C. S. Parish.

DENDROBIUMS.

WHERE a house is set apart for *Dendrobiums* only, it will not be very gay just now, but to the cultivator who studies his plants it is none the less interesting. Nearly all the fine deciduous kinds that give us such lovely blossoms during the spring and early summer months are simply a number of dry, woody-looking stems and cannot by any means be called ornamental. Now they are quite at rest is a capital time to look over the stock and give a thorough cleansing, taking out any old worn-out stems and renewing stakes, ties, and labels. Of course, in this I am speaking of the majority, for some at least of the deciduous and semi-deciduous kinds will be advancing rapidly for flower, others will be in blossom, and a few perhaps may be over. The grand old *D. nobile*, for instance, is one that in the same collection may be had in flower for many months if plenty of plants of it is grown and brought along in suitable batches as required. I have on several occasions seen chance bits at *Chrysanthemum* shows during November, and fine plants often at Christmas. To get them thus early it is necessary that one set of plants be kept for the purpose and grown on as rapidly as possible in the early part of the year, so that by midsummer

or a little later the stems will be finished and the plants placed in a sunny vinery or outside to ripen. But as often as not it is stems two years old that produce these early flowers, in which case the younger ones will not be required, but will keep dormant and bloom the ensuing year. So far as I have noted, the variety has little to do with its flowering early or late, excepting in the case of one or two well-known long-stemmed varieties that are usually later than the majority. A well-known instance is *D. n. Wallichianum*, which may be had quite late in summer.

D. chrysanthum and *D. heterocarpum* are two pretty species that often flower together at this time of year, but they are totally distinct in their manner of cultivation. Both are strictly deciduous, but the former will often flower upon the young growth while the foliage is still fresh, and in any case before resting, while the latter should be well ripened and take a good rest before flowering. Both often grow away in winter, and are, therefore, among the earliest to go back to the growing quarters if removed therefrom to rest. The longer, in reason, these and the long-stemmed *D. Pierardi*, the allied *D. cucullatum*, *D. Devonianum*, and *D. Boxalli* rest, the better, and the same may be said of the beautiful *D. crassinode*, *D. Wardianum*, and many others. From the time the last leaf falls until the plants are again on the move none of these species will require a drop of water provided the growth has been well ripened. But of course there are seasons when it is almost impossible to get them really hard and ripe, and it is at such times that a little moisture at the roots is helpful, preventing shrivelling and subsequent weak growth. The autumn just passed has been all that could be desired in this respect, and my plants of the above-mentioned kinds, also the somewhat erratic and late-growing *D. superbum*, have not had a drop of water for the past six weeks. Plants that often need a little humoring in this respect are the strong-growing kinds of a deciduous habit but that yet carry their foliage through the winter in the majority of seasons. *D. Dalhousianum* and *D. moschatum* are well-known instances. They may be described as evergreen under cultivation, but possibly lose their leaves in a wild state.

The true evergreen species, with club-shaped bulbs and leaves principally at the top, are better for not being kept too dry or too cool during the time that growth is inactive. In fact, were they kept moist only when growth was going on, this would be but a very small part of the year, for many of them will start and finish their growth in about six weeks. They require in fact more regular treatment throughout the year than those above mentioned, and are frequently kept too hot in summer and too cold in winter. It is the same with the lovely *D. infundibulum*—grown in strong heat and rested afterwards. By withholding all moisture it is never really satisfactory, but grow it in an intermediate house the whole year and endeavour to keep it dormant until the sun has sufficient power to ensure solid growth, and it will go on and improve for many years. Its near relation, *D. formosum*, likes more heat while growing, and if this happens to be during winter, the plants must be kept in the fullest light possible. They are always most satisfactory when given an annual routine of growth and rest, and when once a grower gets his plants into this condition, *D. formosum* will improve under cultivation without a doubt. The well-known *D. Phalænopsis* and other lovely kinds from the Australian continent and adjacent islands are

all the better for being kept close up to the glass now that the growths are steady and the flowers either forming or in full beauty. Here, again, the same caution as to rest is necessary. Never distress the plants by withholding water too long, as this only starves the last-made bulbs, rendering it very unlikely that they will ever flower again, and making the resulting shoots weak and easily injured.

H. R.

Epidendrum Brassavolæ.—Of this I have noted a fine plant, and though not a popular species it well repays the little trouble needed in its culture. The flowers appear upon a terminal spike at the apex of the flask-shaped bulbs, and in shape and colour are very distinct. The sepals and petals are yellowish, the lip variable in colour, the usual tint being a purplish rose in front, the base white or orange-yellow. This organ is trowel-shaped, and by it the species may be recognised. The plants do best in an intermediate house in a rough open compost, and must be placed in rather large pots. It is not very constant in its habits, but may usually be induced to rest for a few months during the winter.—H.

Lycaste Skinneri rosea. This pretty variety is now in flower and delicately beautiful in its soft rosy markings, which are intensified about the lip. If this good old species was rare it would be very much run after, for it is one of the finest of cool house Orchids, yet one of the most easily grown. As it is, the plant is almost neglected and one seldom sees it well cultivated. It pays well for liberal treatment, giving it a good substantial compost of light loam, peat, and a little Moss, abundance of water while growing, and a cool, moist atmosphere the whole year round. Then flowers of great substance and in plenty are produced, far different from those on half-starved examples.

Lælio-Cattleya Statteriana.—The parentage of this pretty hybrid is *Cattleya labiata* and *Lælia Perrini*, and though it favours the latter kind most, it is a great improvement on it, the flowers not having that flat, stiff appearance characteristic of the *Lælia*. The colour of the sepals and petals is a soft rosy magenta, the lip bright purple, with a very distinct white throat, which brightens up the flower considerably. With hybrids of this kind—that is, those the result of crossing species a good deal alike in habit and manner of flowering there is little or no difficulty as to treatment, and the hybrid in question is as easy to grow as either of the species. The growth should be induced to come away vigorously in spring and to flower on the young bulb. Then a few weeks of entire rest suits them best, during which time the plants will be kept in the usual *Cattleya* house temperature and given sullee moisture to prevent shrivelling. *L. Statteriana* was raised about five years ago in Messrs. Veitch's nursery.

Odontoglossum Hunnewellianum.—This is an extremely pretty little species, with the habit of a small *O. crispum* and neat arching spikes containing upwards of a dozen medium-sized flowers. They vary a little in colouring, the spots being usually thickly disposed on the segments, which are whitish or yellow in ground colour. The plant is a native of Bogota and is found at considerable elevation, so under cultivation it will thrive with *O. crispum* and similar kinds. The plant flowers at various times in the year, sometimes in spring and again in autumn, and appears to be of the easiest culture. Until well established, the compost should be extremely thin and consist largely of pure Sphagnum Moss, a little peat being mixed with this when the roots are beginning to get well through to the drainage. The best position for all these dwarf growers is undoubtedly one as close to the roof glass as possible, and to avoid any danger of waterlogging, let the pots or pans be as small as possible and thoroughly drained. At no time in the year should the plants be dried off at the roots, only a

diminished supply being given during the dull months, when evaporation is not so rapid as in the summer. *O. Hunnewellianum* is said to have first flowered in Mr. Thompson's collection at Walton Grange about ten years ago.

TREES AND SHRUBS.

AZALEA INDICA ALBA.

THE illustration shows part of a plant of *Azalea indica alba* which is covered with a mass of bloom every year. It measures 12 feet wide, 5 feet high, and is growing in a sheltered position in the flower garden. It has been planted about fourteen years and has not had any protection, although we have had more than 20° of frost on several occasions. T. T.

Creech Grange, Wareham.

The blue Hydrangea.—In common with a good many more growers, I have endeavoured at different times to produce the blue flowers in this by means of various kinds of chemicals, applied both in a solid and liquid form, with varying

Part of an *Azalea indica alba* growing in the open in the gardens at Creech Grange, Wareham. From a photograph sent by Mr. Thomas Tyler.

success, but at the best the colour was a very washed-out one, and not to be compared with the beautiful deep blue tint that one occasionally sees produced by plants which receive no extraneous aid whatever. In the village here there is a fine bush growing by the back door of a cottage and facing due east which produces a great wealth of blossom each year, the colour being a beautiful deep blue. I have known this bush for the past thirty years, and have never known the colour to vary in the slightest degree. The compost in which it is growing is ordinary garden soil, which is rather shallow and overlying a bed of limestone, the latter dipping towards the north. There is nothing whatever in the soil to judge by appearances to cause the flowers to come of such a beautiful blue colour, neither does the plant receive any assistance whatever in the shape of manure either liquid or solid. I have had cuttings from this bush on several occasions, but the plants when they flowered have always been of the ordinary pink colour. This, of course, proves that there is something in the soil where the bush is growing to bring about such a change,

and nothing but an analysis of a sample would reveal what that constituent is. I shall certainly try the compost recommended by E. Bar (see *THE GARDEN* for December 3, p. 457), as it has the merit of being extremely simple and inexpensive, and it will be interesting to watch results. Perhaps some other readers of *THE GARDEN* will also be induced to give it a trial after perusing the note alluded to and report thereon in due course.—A. W.

Skimmias.—When the dull weather usually associated with the end of autumn sets in, one has to search for the brightest outdoor features among the berried trees and shrubs of which our own native Holly furnishes such a well-known and popular example. The brightly-coloured berries of the *Skimmias*, too, are greatly admired. Being evergreen, *Skimmias* are largely used, particularly since the improved forms have become generally cultivated. All the *Skimmias* are very beautiful, but the finest of all is that known as *Foremani* (a garden form), which first had public attention directed to it ten years ago, when it was shown in grand condition and received a first-class certificate at the December meeting of the Royal Horticultural Society. The berries of this are borne in great profusion, are very brightly coloured, and remain in good condition a long time. The habit of the plant is free, yet compact, while the foliage is all that can be desired. *Skimmias* are largely used in London for furnishing window boxes, balconies, and similar purposes, and, provided reasonable attention is given them, they are less affected by the smoke-laden atmosphere than many other evergreens.—T.

OUR WOODLAND WALKS.

As one rambles through the woods during the autumn it is impossible not to be attracted by the varied hues and forms of the fading leaves of our forest trees and the underwood, particularly in districts where the *Viburnum*, *Cornus*, and *Rhamnus* abound, and where the wild Cherry and Crab are plentiful and the peculiar berries of *Euonymus* hang from their slender stalks. But none of these are to be compared with the foliage of some of the trees and shrubs brought from other lands. The scarlet Oak, for example, which usually retains its leaves long after most of the other forest trees are bare, with its large bright foliage is very conspicuous. The leaves of many of the Maples, together with those of the *Liquidambar*, also tend to brighten the scene. No one can help admiring the stately trunks of trees either when standing alone or in groups; but, unfortunately, it sometimes happens that those whose duty it is to look after these set no store by the venerable trunks. They have but one aim in view, and that the commercial one. The stately trunks to them mean so much money: therefore the woodman is set to work, and down come the trees that have been so much admired for generations. The Oak, the Pine, the Beech, and Ash are all sacrificed to the woodman's axe. Such are nothing for their worth as noble adornments to the domain or for the beauty of their foliage and flowers. True, there are some places where noble trees are still admired. Still, it does not appear there is that interest taken in the planting of ornamental trees and shrubs in many places one would expect. There are many bare places that might be turned to good account if those in charge did but understand the work. The small belt required for ornamental shrubs alongside the carriage drives, by the edges of

streams that in some places flow through the woods, or by the paths would not take up much room, but, if judiciously planted, might prove a source of enjoyment and pleasure to their owners and friends. There is no necessity for keeping these woodland walks in that prim order one is accustomed to see in grounds in close proximity to the mansion. What is needed is to open up interesting vistas, giving more prominence to extra fine trees; not by lopping off branches indiscriminately, but by a judicious thinning out where needed. It is not the size of a place, but the manner in which it is laid out that gives the greatest pleasure. There are many places where much might be done at little cost to effect great improvements, and what are now bare, unsightly spots might be turned into interesting sheltered nooks where many choice plants and trees could be planted. B. P. S.

AUTUMN FLOWERS AND FOLIAGE.

THE mild weather in October and during the greater part of November has again forcibly brought to our notice the value of late-flowering plants, both shrubby and herbaceous, also the glorious effect that may be produced by a judicious selection of deciduous trees and shrubs for planting alongside woodland walks and in places where their varied autumn tints can be seen to advantage. Of flowers there has been no lack this autumn, for in sheltered situations the Dahlias were not cut down until the latter part of November, and Tea Roses have seldom been seen in such profusion so late in the year, as until the night of November 22 fine fresh blooms were gathered in abundance from bushes growing in the open. Since then we have had exceptionally severe and rough weather, as many as 14° of frost being registered, which have quite put an end to their beauty. Some plants of *Cassia corymbosa* were flowering most profusely in a sheltered situation until the date above-named, the clear yellow flowers showing up wonderfully above the bright green foliage. We too seldom see this plant well grown, and no idea can be had of its beauty from small plants in pots. When planted out in the open in beds of rich soil and allowed to ramble, strong growths are made, which produce an abundance of bloom on their terminals late in the season. This plant is not hardy, but may be planted out in summer with other half hardy shrubs, when it will well repay anyone for the little trouble required to protect it during the winter. A good companion is the old *Erythrina crista-galli*, though flowering somewhat earlier in the season. *E. laurifolia* and some others of the same genus also do well out of doors in the summer when liberally treated and afforded protection during the winter months. *Aloysia citrodora* is usually to be seen treated as a greenhouse plant, but this, too, makes a charming subject for summer bedding or for planting in clumps in the wild garden, as its shoots when liberally treated will grow from 6 feet to 7 feet long in one season. Where room can be afforded in a cold frame the plants may be taken up when cut down by frost and stored away for the winter. In spring they should be cut down to within 6 inches of the previous year's shoots and started in a gentle heat, when they will make fine plants for putting out in June. As the points of the young shoots root so readily in heat, it is not necessary to keep the plants longer than one year, for if cuttings are rooted early the plants will be sufficiently advanced in growth for planting out as soon as all danger of frost is over. *Swainsonia* make grand subjects for planting out in sunny positions, as in such they flower till quite late in the season. They are easily propagated either by seed or cuttings. *Desfontainia spinosa* is another grand old plant that produces an abundance of bloom in the autumn and early winter months. In some sheltered places this will withstand the rigour of our winters; it is, however, better to protect it in a cool house. *Abutilons* of various kinds are also fine autumnal flowering plants when given liberal treatment

during the summer, and as they will stand such rough usage in winter by being stored away in a cold frame are most accommodating.

We are apt to pay too much attention to tender, soft-wooded plants that are cut down by the first severe frost instead of looking more to those which, though not quite so showy in the early part of the season, do much to enliven our gardens during the latter months. There are many plants too that might be grown for the beauty of their foliage alone, to say nothing of the wealth of flowers that some of them give us. The leaves of the purple Vine, for example, hanging to their slender stems have been beautiful this autumn; so have the leaves of the scarlet Oak, some of the Maples, Barberries, and *Andromedas*. We are too apt to think only of the summer adornment of our gardens, leaving them by far too much alone in autumn and winter, but there are many interesting hardy plants suitable for planting alongside shrubby paths and wilderness walks which, though not producing brilliantly coloured flowers, are, nevertheless, attractive during the dull winter months by their peculiar habit of growth and varied forms of bark, and even in some by their singular foliage, which clings to them until the young leaves displace them in spring. H. C. P.

Raphiolepis salicifolia.—For covering a wall in a somewhat sheltered position this pretty Chinese shrub appears well suited, being neat in habit and producing rather freely its small panicles of white flowers. A position sufficiently favoured to suit such things as *Ceanothus* would probably answer for this plant.—E. J.

Vitis heterophylla humulifolia.—The issue of THE GARDEN for November 26 was especially interesting to me owing to the several references to *Vitis* it contained. The illustrations make one long to be placing poles and planting Vines to cover them in every direction. But what I wish to refer to is the above Vine. Some years ago I received a small plant of it together with a bunch of fruit from the Rev. H. Ewbank. In due time I planted it in good soil in a warm corner, sheltered from east and north—in fact, one of the warmest corners I could find here. From some reason I am unable to explain it never began to grow until the past summer, when, to my delight, it started very early in the season, making several growths each varying from 10 feet to 12 feet in length. On the top of the wall against which it is planted is a wooden trellis, the top of which it has reached. I fear in the event of severe weather all this growth will perish, and that in consequence I shall not see it fruit next summer. With regard to the remarks Mr. Bean has made re *Vitis Coignetiae*, I trust that it will not continue to behave as it has for the past three years here, viz., keep perfectly green until the leaves fall in autumn. I cannot complain of the amount of growth it has made. This is quite satisfactory, and applies to half a dozen plants. Some of the cut-leaved varieties are delightful, and should be planted more extensively on old tree trunks, up poles, and such like places. I was lately reading a glowing account of *Vitis inconstans*, and determined to order one for a particular place on the house here. I searched several catalogues, and should certainly have remained in ignorance of the plant referred to had I not noticed Mr. Bean's reference to it.—A.

* * * Ever since the name was altered we have, when writing of *Ampelopsis Veitchi*, used the new name *Vitis inconstans*.—Ed.

Outdoor labels.—The following system I have adopted for some years with perfect success: I get zinc cut into the sizes required and clean them with fine emery paper, rub smooth with a leather, and write on them with the indelible ink somewhat thickly. When perfectly dry I give the labels a coating of carriage varnish. The weather never injures the writing, and I have seen some thus treated which have been used for

eighteen years, and as clear as the day they were first written.—M.

KITCHEN GARDEN.

FORCING POTATOES.

POTATOES are always appreciated when forced, though hard forcing affects the quality, and it is to this point I would call attention. There are matters equally important, and one is that the top-growth must not be too much in advance of the roots. This is caused by hard forcing, and the crop grown thus at times does not pay for space occupied. For supplies in the early part of April now is a good time to make a start, and it is surprising how well the Potato can be grown in pots if the latter are not too much crowded with sets at the start. I have, to get an extra supply, found growing in pots most useful, as the pots give little trouble. Tubers potted now and placed in a forcing house—or what is better, the front part of a fruit house started some weeks ago—will give an earlier crop than the frame roots. Size of pot is not important. I prefer 10-inch or 12-inch pots, as this is a useful size, and it is an easy matter to move them from one house or frame to another. I am aware many use much larger pots, but they have to remain in one place, and if very small ones are used the soil soon dries up when there is a good top-growth, so that anything smaller than 8-inch pots I do not advise. Many growers prefer to get the sets sprouted previous to planting, and it is well to do so, but not too much, as if the sets have made roots there is no gain whatever, as they suffer badly when shifted from the boxes where started and transferred to pots. I have noticed when too much advanced they make one fair-sized tuber and the others are too small. They may be started say a fortnight or three weeks in advance of potting up or placing in frames. The shorter period is quite enough if the seed was well prepared for forcing by exposure after lifting. For seed from a clamp a longer period would be needed to start the sets. Another point worth attention is the variety forced. There are now some excellent kinds, and these I prefer to the old Ashleaf type, as they give a heavier crop and force quite as readily. One I grew largely last season was *Ninety-fold*. This is a splendid kidney, having a strong but dwarf haulm, and the quality is equal to that of the best of the Ashleafs, the flesh white, floury, dry, and of delicate flavour. *English Beauty* is also a favourite with me for pots and frames. This is a heavy cropper and of good quality. In this there is a good deal of the *Beauty of Hebron*, and it is one of the best croppers I have grown. This variety has been a success in other gardens, as some good accounts of it have appeared in THE GARDEN. Many prefer the Ashleaf kinds on account of their short top and distinct flavour. They have no equal in the latter respect, but at times the crop is not so large as one could wish. For years I grew *Sharpe's Victor*, but now rely on the two kinds mentioned above.

When grown in pots the sets need a good soil. If heavy, I mix burnt wood ashes or spent Mushroom manure with a portion of bone-meal, and make the soil firm when potting. If too light, the plants make a poor root growth. I advise filling up the pots at the start, as there is no gain whatever in heavy top-dressings. I find the best food is that in a liquid state or in the shape of a fertiliser. Growth is too rapid to benefit by top-dressing, and often the new soil added keeps the lower soil dry. The

varieties named if potted up in the early part of January will be fit for use in thirteen weeks if the sprouts are about half an inch long when potted. I always endeavour to keep the tops dwarf. This is a necessity, as a drawn top will mean a poor crop. The plants must be near the light, and be given plenty of air in fine weather. In frames much the same advice applies. Three or four sets in a 10-inch or 12-inch pot are ample. A better crop for first supplies from frames will be obtained with bottom-heat, but the warmth must be moderate. Many crops are poor in consequence of too much warmth at the start. I never like to hurry the growth. I find fresh-gathered leaves excellent material for bottom-heat, and, if needed, manure may be added, but it is far better to give a little more time and force slowly than to force hard. Many are independent of heat from manure or leaves, having hot-water pipes, but there is danger of dryness at the roots from these. In frames I find it best at the start to give the beds the full quantity of soil needed, that is sufficient to allow of moulding up as soon as the top growth is large enough. At least 12 inches to 15 inches should be given, this being placed in the frame in time to get warmed through before planting. In cold weather it is a good plan to cover the frames at night. The heat at night should not range higher than 55°, with 10° more by day. Cold draughts are bad, as these make the haulm near the soil lose vigour, the leaves turn yellow, and once a check is given the plants cease to tuber.

For later supplies I have used turf pits to great advantage; indeed, this old system, though now little practised, was one of the best. In such I obtained the best tubers. Others, again, may have cold frames, and tubers planted early in the year will give good crops late in April or early May. In the planting of tubers without heat of any kind other than glass protection, it is well to use good sized sets. It is also advisable to well ripen the seed and give good soil, well enriched not so much with manures as with fertilisers, giving liquid manure as growth is made. G. WYTHES.

Christmas salad.—This is doubtless a fine selection from the Witloof Chicory, a root much grown on the Continent, not only as a salad when blanched, but as a vegetable. For the latter purpose it is much liked if the shoots are not grown in too much heat and cut like Sea-kale before they expand. This plant grows so freely in almost any soil that there is no difficulty in having a good lot of roots for forcing from now to March. Forced in a dark place in a temperature of 60° the plants produce a lot of salad material. If used as a vegetable the growths should be cut before they get more than 4 inches or 5 inches long. In the winter when Lettuces are scarce, the tops of this plant when blanched make a valuable addition to the salads in season.—S. H. B.

Lettuce Record.—A few seasons ago I tried several of the well-known hardy kinds of Cabbage Lettuce, including Record and The Intermediate, the latter more of a Cos than a Cabbage variety, but one of the hardiest varieties I have grown and a distinct break from other types. The Record is not unlike the well-known Tom Thumb, but larger. It resembles the Brown Standwell in colour, having dark brown leaves, and the quality is excellent. These brown leaved types are the hardiest, and Record being a medium grower is one of the best. This variety winters on a sheltered border without any protection. I grow it in hot weather on account of its long standing. Record stood the severe drought last summer much better than summer varieties. There is no lack of varieties of Lettuce, but none too many

really good hardy kinds, and this one is well worth adding to the list for either summer or winter use.—G. W.

Hardy Cabbage Lettuces.—Although several of the more recently introduced varieties of small Cabbage Lettuce are an advance on the older forms so far as early maturity is concerned, it is doubtful if there are any to equal in point of hardiness. All the Year Round and Hardy Hammersmith. If either of these is planted some 6 inches apart in a well-glazed, drip free frame in October, the soil being brought up to within a foot of the glass, and a little protection given in very severe weather, they will grow steadily through the winter and form nice heads in early spring. It is also a good plan to plant a row or two at the foot of a south or west wall to come in after the frame batches and before the Brown Cos. In case of very sharp frost they will need a little protection.—B. S. N.

The Tree Tomato.—As an ornamental plant many could grow this, but for use I fail to see its value. Some years ago this was exhibited at a meeting of the Royal Horticultural Society and did not find many admirers, as very few who tasted it cared for it. It is by no means a profitable plant to grow. Mine was quite two years before it fruited, and those who picture this variety as somewhat similar to a Tomato will be somewhat disappointed. I do not think it out of place in a collection of plants. It is interesting, I admit, and in these days when cost of production is a cardinal point in most gardens, I fear the Tree Tomato will not become a general favourite. It would be worth trying to see if fruiting could be hastened by taking cuttings from fruiting plants. This would be a gain, and probably a much dwarfed plant needing less space would result.—F. R.

Cauliflower Early Dwarf Erfurt.—This Cauliflower has been for many years before the public, and I think it still one of the very best for first cutting to follow the late Broccoli. There is no great difficulty in having a succession of Broccoli and Cauliflower if the latest kinds of the former, such as Model or Late Queen, are grown, with the Early Dwarf Erfurt Cauliflower as a first crop in the open to follow the Broccoli. Unfortunately, there are some poor types of the Erfurt, one I had being greatly superior to others I grew. The one named is very distinct, having a dwarf habit than many early kinds; at the same time the flower is of a good size, pure white, and firm. It is certainly one of the best for autumn sowing, as it stands our winters well. I put up many hundreds of plants for early cutting. I find much better heads are obtained when the seeds are sown in the autumn.—S. M.

Wintering Cabbage plants.—I am afraid that in the majority of gardens not only good winter, but also spring supplies of green vegetables and Broccoli will be none too plentiful. As long as small heads of Broccoli are forthcoming one is satisfied, but this autumn such havoc has been wrought by caterpillars that even small heads of good quality will, I expect, be the exception. The most then must be made of plantations of spring Cabbage and care taken of those now in the seed-beds, as the earliest transplanted batches, equally as much as Cauliflowers, will be likely to bolt in spring, especially on light soils, and should the rainfall this winter be small and the spring dry, I would strongly advise making a late planting in frames and protecting open-air seedlings in case of severe weather, also earthing up permanently-planted quarters. One of the best safeguards against bolting and other mishaps is to grow several sorts, if only a few rows of each.—J. C.

Young Cauliflower plants.—After such a peculiar season, young Cauliflower plants raised for the production of heads in spring or early summer will be very liable to behave strangely. It will therefore behoove those who would avoid disappointment to have more than one string to their bow. It is not always that the cream of the seed-bed which is carefully planted in frames or pits comes out the best in the end, although that

is the only really safe method of wintering the plants. With a mild winter the second-sized plants left out on the border may prove invaluable next season, and I would advise those who have them to give a little extra trouble. It will be well to make a second planting into frames, and though rather late for the work, if a goodly number are planted closely together in a bed on a warm border and a rough frame erected over them so that protection can be given, it will be better than leaving them in the seed-bed, as they become leggy and never transplant so well.—C. N.

July-sown Carrots.—A large breadth of Early Scarlet Short Horn Carrot sown about the middle of July is very acceptable just at present, with choice outdoor vegetables none too plentiful. The border where they are growing was cleared of a crop of William Hurst Pea, well manured and deeply dug, and after lying a day, had a slight treading to settle it. The weather at the time of sowing was very dry, so the drills were drawn in the afternoon after the sun was off the border, and received a good soaking, the seed being sown and covered in early the following morning before the ground had dried. The young plants came away well and the roots are now about an inch in diameter—just the right size for table. With sowings in a frame in January, and in the open respectively in February, April, and July, young Carrots are obtainable nearly all the year round and may be grown in all gardens. The January sowing should be made on a bed of leaves. If sufficient can be obtained to build up the bed 4 feet or 5 feet high, so much the better. Manure can then be entirely dispensed with, and the warmth, although not strong, is long retained.—E. BUCKELL.

Potato Beauty of Hebron.—Beauty of Hebron is a Potato which has stood the test of time, and, as with that favourite of Mr. Tallack's, Snowdrop, it may be used as early as the beginning of June, and yet will keep sound and good until the new year has considerably advanced. It is true that in wet seasons and in strong soil it is rather liable to disease, but this season should have suited it, and from the light soil of this district it has this summer lifted in grand condition, its floury texture and sweet nutty flavour being such as all Potato lovers appreciate. As a cropper it is hard to beat, this being one of the reasons why market growers having light soil still grow it largely for the London and other markets. The articles by Mr. Tallack and Mr. Prinsep on the Potato crop in their respective gardens will have been read with interest by others besides myself. I am pleased to read of the newly-introduced variety Syon House Prolific maintaining its good reputation, also that Mr. Tallack still clings to some of the good old sorts, as I think it is a pity really sterling varieties should be pushed out of cultivation by very often inferior sorts.—NORWICH.

Late runner Beans.—Seldom have these been in good condition so late in the season as this year. I had a continuous supply till November 5, and this from tall runners without any protection except the shelter of some high trees at a distance. I thought I was exceptionally fortunate, but to my surprise I saw a half-sieveful of nice Beans in a greengrocer's shop in Camberley several days later. On asking where these had been grown, I was told, in a garden near by. This goes to show the advantage of not relying on one sowing if a long supply is wanted. For years I have made two or more sowings and generally found it paid. Runner Beans will continue bearing a long time when they are grown on highly cultivated ground and the Beans kept gathered before they get old. My first row is sown on this kind of land, and this season they went to the tops of 12 feet stakes, and would have reached 3 feet more had the stakes been high enough. But from these the supply diminished considerably as the autumn came on, and those sown about June 15 gave the best results for late work. It is a good method where the land is good to sow after the first Potatoes are dug, allowing them to run over sticks laid on the

ground, as in this way they can be protected.—DORSET.

Large Onions.—In his somewhat severe criticism of some recent remarks of mine concerning large Onions, "Onion" seems to have materially misunderstood me. My complaint as to certain large Onions obtaining prizes related to making awards by weight only, and not by appearance, thus granting to mere size what was meant for beauty, solidity, freshness, evenness, and keeping excellence. Not only were the heaviest Onions in question discolored, but the skins were devoid of that finish which should always characterise bulbs of the highest excellence. To assume that because I deprecate the practice of allowing the scales to determine excellence in Onion bulbs on the show table, and not the knowledge and intelligence of the judges, and that I want to place a mere ordinary sample before huge bulbs produced by the new culture is absurd. Still, even in that case "Onion" must not be too certain that greater weight from a given area is obtained from a planted-out Onion crop 2 feet apart than from one from a spring or autumn sowing giving twelve bulbs in the same space. But after all, that is beside the question, and I have no intention to deprecate the new culture which leads to the formation of great 2-lb. to 3-lb. bulbs. But when these fine bulbs have to be judged, let not mere size or weight govern the decisions. The points I have named above after all are much more meritorious; indeed finish, beauty, solidity, and keeping qualities are in all these Onions of primary importance, and should never be put aside for other considerations.—A. D.

The Cabbage fly.—In THE GARDEN of October 15 and November 5 the question of *Anthomyia brassicae* and elubbing in Cabbages was dealt with. "G. S. S." is quite right that there is no connection between the two. I have found no difficulty in dealing with the elubbing, but am still searching for a remedy against the *Anthomyia*, which destroyed nearly all my *Brassica* crops this year. I have found that here the fly causes little damage except in dry, hot weather, such as we had last summer. My own belief is that all treatment of the evil—soot, lime, &c.—is of no use. The fly may be hatched elsewhere. It lays its eggs in the Cabbage-stalk; the grub is hatched and does the damage before coming into contact with the ground. I am convinced that the remedy lies in some preparation applied to the stalk of the plant itself to prevent the fly laying its eggs, or to kill the grub as soon as hatched. I have tried many things. Paraffin seems to give protection for a short time, but is not a cure for the evil. I should be very glad to know if any of your readers have discovered a remedy for this pest.—HUBERT CONGREVE.

* I quite agree with the above remarks about it not being of much use to treat the soil in the case of Cabbages, &c., attacked by the Cabbage fly (*Anthomyia brassicae*), and that it would be of more use to coat the stems with something that would keep the flies away, if such a compound could be found. From the fact of this insect doing more harm in dry weather than in wet, it is probable that the flies are more abundant in fine weather than in wet. Perhaps painting the lower parts of the stems with a thick whitewash, or a mixture of a similar consistency composed of soil and nitrate of soda, might be useful, provided it did not injure the plants.—G. S. S.

NOTES AND QUESTIONS.—KITCHEN.

Coprinus comatus.—I presume that the fungus described in THE GARDEN as the tall or cylindrical *Agaricus* is *Coprinus comatus*, the flavour of which is considered by some superior to that of the common Mushroom when cooked. It also is said to make most excellent sauce. A few days ago a large quantity of it appeared in patches near the S.W. Railway between Clapham and Wandsworth. In this fungus the spores are black, and the cap, at first cylindrical with a

rounded top, becomes gradually slightly conical by expanding below.—E. M. HOLMES.

Pea May Queen.—During November I saw an excellent dish of this Pea sown in heavy soil in June specially for late dishes. For some three years I have grown this variety on account of its good qualities and earliness. There is a distinct trace of the Marrow in it and it is one of the earliest Peas I have grown. Sown side by side with others noted for their earliness, this one was ready by the third week in May, and what is so important to growers, the Peas are of a nice size and of good quality.—S. M.

GARDEN FLORA.

PLATE 1201.

THE SHRUBBY ST. JOHN'S WORTS.

(HYPERICUM.)

(WITH A COLOURED PLATE OF *H. MOSERIANUM*.)

CONSIDERING its size and the really ornamental character of many of the species and varieties, the genus *Hypericum* is but poorly represented in gardens. There are in all probably upwards of 200 species, and whilst most of these are

Hypericum Hookerianum (syn., *H. oblongifolium*).

either herbaceous or too tender for this climate, and therefore do not come within the province of the present paper, the hardy woody ones that remain constitute a useful and desirable group. It is true that these *Hypericums* present but little variety in the colour of the flowers, for they are all of some shade of yellow; but they vary a good deal in height, mode of growth, and in the size and character of the flowers and leaves. To my mind the great value of the St. John's Worts is in the time of year they flower. A few of them are in bloom by June or early July, but most of them are still at their best in August, and they keep on flowering till the end of September and, in suitable seasons, till October. It is during these months that the absence of flower amongst trees and shrubs is most apparent.

Next to their yellow colour the most noticeable feature of *Hypericum* flowers is the num-

ber and length of the stamens. These are united into three or five bundles, which, together with the number of divisions in the seed-vessel, afford botanists important distinctive characters. The leaves of many species are distinguished by a number of pellucid dots, more especially crowded near the margins. The smaller species are suitable for the rock garden, while the taller ones are seen at their best planted in groups towards the front of the shrubbery. None of them require the soil to be of more than moderate richness. They can be propagated by seeds, cuttings or division. Some of the species mentioned in the following notes are not absolutely hardy except in the warmer counties, and during hard weather some covering should be provided. A layer of dry leaves thrown lightly over the roots and around the stems, and kept in place by a Spruce branch, is a good covering, and is not at all unsightly.

The following list does not include all the species that are, or have been, in cultivation, but it includes the best of those that are available. Those marked * are the more tender sorts:—

EUROPE (INCLUDING MEDITERRANEAN REGION).	
* <i>Egyptiacum</i> .	Elatum.
<i>Androsæmum</i> .	* <i>Empetrifolium</i> .
* <i>Balearicum</i> .	<i>Hircinum</i> .
<i>Calyceum</i> .	* <i>Olympicum</i> .
ASIA.	
Aseyron.	* <i>Patulum</i> .
<i>Hookerianum</i> (syn., <i>H. oblongifolium</i>).	* <i>Uralum</i> (syn., <i>nepalense</i>).
<i>Inodorum</i> .	
AMERICA.	
Aseyron.	<i>Galioides</i> .
Aureum.	<i>Kalmianum</i> .
Buckleyi.	<i>Prolificum</i> .
<i>Densiflorum</i> .	

H. MOSERIANUM is a hybrid.

H. EGYPTIACUM.—In sheltered situations and with the help of a little covering this species has survived hard winters in this country, but it is, nevertheless, one of the less hardy sorts. The specific name is misleading, for although it has an extensive range over the Mediterranean coasts and islands, it has never been found truly wild in Egypt. It is a dwarf shrub with tiny pointed leaves each from one-eighth of an inch to a quarter of an inch long, crowded very thickly on the branches. The flowers, borne singly at the ends of the numerous lateral twigs, are of a pale golden-yellow, and three-eighths of an inch across. Only the terminal half of the petals is spreading, the lower half of the flower being somewhat tubular. The plant is a singularly pretty one both in its foliage and in the profusion and brightness of its flowers, and it is a pity it is not more hardy. At Kew it has been most successfully grown out of doors at the foot of a south wall, with a covering of some dry material in winter. It is now a rare plant, although it was introduced in 1787.

H. ANDROSÆMUM (Tutsan).—Whilst in its foliage and in its fruits this is one of the handsomest and most striking of the *Hypericums*, it is somewhat deficient in regard to the beauty of its flowers. It is a shrub of robust habit, growing from 1½ feet to 3 feet in height. In cultivated specimens its broad, ovate leaves are occasionally close upon 4 inches in length and of a rich dark green. It bears its flowers in cymose clusters at the ends of the main and lateral branches; from three to twelve are in a cluster, and each one is about three-quarters of an inch across and of a light yellow. The flowers are followed by handsome black-purple, pulpy berries, each about the

size of a pea. The species is a native of Europe. It has been found wild in the south of England and in the west of Scotland, but is rare. It flowers from the latter part of June to September. The popular name of Tutsan is a corruption of the French "Toute-saine" (Heal-all), and refers to the many curative qualities the plant was at one time supposed to possess.

H. ASCRON is a somewhat coarse and ungainly species, which is chiefly interesting in being a native of both North America and of Northern Asia. It grows from 2 feet to 5 feet high, has

Hypericum potulum.

narrow leaves averaging 3 inches in length, the base of which partially clasps the stem. The flower is 2 inches across, with curiously shaped narrow petals. Towards autumn the plant is apt to become rather unsightly through the lower leaves dying and remaining on the stems. It is semi-herbaceous.

H. AUREUM.—Of the New World species this is the most attractive—at least as regards its behaviour under cultivation here. It is an erect bush of rounded form, eventually attaining about 4 feet in height, and more distinctly woody than most *Hypericums*, its lower branches often falling away and giving it the aspect of a miniature tree. The leaves are rather glaucous and leathery, and each from 1½ inches to 2 inches long. The flowers are orange-yellow, and each about 1½ inches across, with a large and conspicuous mass of yellow stamens filling the centre. Here it generally commences to flower during the latter days of July or the earlier ones of August. The fruit has the shape of a pointed cone and is three-quarters of an inch in length. The species is a native of the South-eastern States of North America, and was first discovered by Bartram in July, 1776, "upon the steep, dry banks of Patse-Lega Creek, a branch of the Flint River, in Georgia," where he describes it as being of extraordinary beauty. It appears to affect rocky situations in its native state, and is often to be seen on the cliffs of river-courses, generally where it gets some shade. There is a good figure of it in *Garden and Forest*, 1890.

H. BALEARICUM.—Like *H. aegyptiacum*, this is one of the rather tender Mediterranean species, and requires protection and careful watching if cultivated in the open in this country, as might, indeed, be expected of a plant from the Balearic Isles. It is not only a pretty little shrub, but also one of the most distinct and interesting.

From all the other species here mentioned it can easily be distinguished by its leaves; these are each half an inch long and oblong, the lower side having numerous little raised, wart-like lumps irregularly arranged. Corresponding to each of them is a scar-like depression on the upper side. The young branches have also the same warty character. The bright yellow flower is 1½ inches across, and has rather narrow petals and numerous long, thin stamens. The first recorded introduction of the species to Britain was in 1718, when seeds were sent from Minorca by an apothecary of Barcelona named Salvador, but from information left by Chusius, the botanist, it seems to have been known here long before—as far back, indeed, as 1580. It is abundant also in the larger island of Majorca.

H. BUCKLEYI.—It is only some five years since this *Hypericum* was introduced to this country, seeds having been sent to Kew by Professor Sargent in 1893. The plants thus obtained flowered in 1895, and seedlings have been obtained from them. It has already proved a charming little shrub, quite distinct from any we previously possessed, and the smallest of the hardy species. It is rather like some of the dwarf *Veronicas* in habit, and is admirably adapted for the rock garden, forming neat rounded tufts only a few inches high. On the small plants at Kew the leaves are each about half an inch long, broad and rounded at the apex, but tapering to a short stalk at the base. They are closely arranged on the very slender four-angled twigs, each of which bears a single flower at the top. The bright yellow flowers are each 1 inch in diameter and appear from early July onward. According to Professor Sargent (who figured the species in *Garden and Forest* in 1891), this pretty and delicate plant is one of the rarest of American shrubs, and is only known to exist on a few of the higher mountains of the Carolinas and Georgia, where it was discovered by Mr. Buckley many years ago. The plant is described as wide-branching, with stems 8 inches to 12 inches long, and the leaves appear to get considerably larger than they have done here as yet.

H. CALYCINUM (Rose of Sharon).—Taken altogether, this is the most beautiful and useful of the St. John's Worts. Its flowers are the largest, it is a plant of very vigorous habit, and near London, at all events, there is no question as to its hardiness. It is a native of the Levant, but has now become naturalised in several parts of the British Isles. It has a creeping rootstock and spreads rapidly in well-worked soil. From the ground the stems (mostly unbranched) rise in a thick mass 1 foot or more high and bear several pairs of dark green leaves, each measuring 2 inches to 3 inches in length. The flower, borne at the top of the stem, is solitary, and from 3 inches to 4 inches across, the colour a bright golden yellow. The flowering season extends over July, August and September. This is an admirable under shrub, thriving well in moderate shade and making a dense carpet of richest green. It is evergreen except during our hardest winters. Besides the popular name given above (which is the prettier), it has been called "Aaron's Beard," from the number and length of the hair-like stamens.

H. DENSIFLORUM.—Whatever it may be in its own country, this *Hypericum* can only be described as of secondary importance as a garden plant in this. It is a native of the Pine barrens of the South-eastern United States, and is a shrub averaging 3 feet to 4 feet in height. It has numerous erect branches, whose leaves are made to look still narrower by the revolute margins. The flowers, each half an inch across, are numerous borne in broad, compact clusters. The species is variable as regards its foliage, a broad-leaved form being very like *H. prolificum*, under which species it was at one time placed by Asa Gray. The form with which I am acquainted is more like *H. galioides*, but it differs from this in the structure of the seed-vessel.

H. ELATUM.—Of our cultivated St. John's Worts, this is, in my experience, the most vigorous and robust. It grows some 5 feet high

and is furnished with foliage of the deepest green, its broad ovate leaves being 1½ inches to 3 inches long. The flowers are not proportionate to the plant in size, being generally about 1 inch across; they appear, not many together, in cymose clusters, but the clusters themselves are abundant. The plant is very handsome in autumn, bearing freely at that time its dark brown fruits, which are at first fleshy like those of *H. Androsimum*, only longer and less rounded. As regards its flowers alone, it is less handsome than *H. calycinum* or *H. Hookerianum*, but its vigorous habit and handsome appearance make it a very useful shrub. It is now naturalised in some parts of Britain and Ireland (Cornwall, Argyllshire, Co. Down, &c.), but is not a true native of these islands. Loudon and others have given it as American, but this is an error. It comes from the Canary Islands.

H. EMPETRIFOLIUM.—Two years ago last September, whilst visiting Messrs. Dicksons' nurseries at Chester, I was charmed with a large patch of this little *Hypericum* in full flower. There were scores (possibly hundreds) of plants all about 6 inches high, as neat as young Heaths

Hypericum empetrifolium.

in growth, and covered with the pale golden-yellow flowers. Unfortunately, we are not able near London to keep it permanently out of doors. It survives the milder winters, but the entire stock should never be left outside, a few being potted up and put under cover. It is a Mediterranean plant, coming from the islands of the Grecian Archipelago and the shores of Greece

and Asia Minor. In this country one sees it, as a rule, under 1 foot in height, although in its native home it gets to be taller than that. It has erect stems and small, narrow, Heath-like leaves half an inch or so long, arranged in threes at each joint. The flowers, each about two-thirds of an inch across, are borne freely on slender, erect, branching spikes. The species, which is as pretty as it is distinct, was introduced by Lee, of Hammersmith, in 1788. It is used for the greenhouse at Kew.

H. GALIODES.—More than 100 years ago this plant was in cultivation in the National Garden at Paris; but in spite of this and the fact that it is one of the most ornamental species in America, it has never been much cultivated in Europe. Possibly this and other American species do not adapt themselves perfectly to our climate, for they are certainly far inferior to the majority of the European and Asiatic species. *H. galioides* is a bush about 3 feet high, with leaves each $1\frac{1}{2}$ inches long by only one-eighth of an inch in width. The flowers, each three-quarters of an inch across, are produced in small clusters at the ends of the shoots and in the axils of the uppermost leaves. It is a native of the South-eastern United States, and flowers from July to October.

H. HIRPINUM.—The most distinguishing character of this species is the goat-like odour of its leaves when handled. To this it owes its specific name. In spite of its somewhat evil odour the plant itself is a handsome one. It flowers very freely over a long period (from early August to October), and its foliage is abundant and of a deep green. The plant is also perfectly hardy, and altogether one of the most robust of the St. John's Worts. It is a bush 2 feet to 3 feet high, which branches very much towards the top of its stems, every one of its ramifications bearing several flowers, bright yellow and each $1\frac{1}{2}$ inches across. It is a native of the middle latitudes of Europe, and was introduced to Britain in 1640. According to Syme in "English Botany," it is naturalised in the Haughley Woods, Norfolk, which is one of the best evidences of its vigour. *Var. minus* (*H. minus*) has smaller leaves and flowers, and is itself a much dwarfier plant. It is, nevertheless, as pretty and free-flowering as the type, and for some situations—in a rock garden, for instance—would often be preferable.

H. HOOKERIANUM.—One of the first places among *Hypericums* undoubtedly belongs to this species. Of the taller-growing ones it certainly has the most beautiful flowers. The leaves are each 1 inch to 3 inches long, almost or quite without stalks. Its first flowers are open in the early days of August, and it continues to bloom for the next eight or ten weeks. Even as late as the end of October a good bouquet could have been gathered from the plants at Kew. The flowers, of which there are several in a cluster, are each 2 inches across, of a rich golden yellow, the concave shape of the broad, full petals rendering them rather cup-shaped. It grows on the Sikkim Himalaya at 8000 feet to 12,000 feet above sea-level, also on the mountains of Assam. It was from the latter district, near Mullang, that it was introduced by Lobb. I have not seen it more than 4 feet to 5 feet high, but it is said to grow 8 feet high in India. It is easily increased by cuttings, and ought more frequently to be grown. The species is sometimes known as *H. oblongifolium*, under which name a coloured plate of this plant was published in *THE GARDEN*, Sept. 4, 1886.

H. INODORUM.—As regards its habit merely, there is no more elegant *Hypericum* than this. It grows from 3 feet to 4 feet high, and forms a dense and very graceful mass of arching or pendulous branches luxuriantly furnished with leaves. It does not, however, flower with the same freedom as most of the St. John's Worts. It bears its flowers in small terminal clusters, and each blossom is 1 inch across. The leaves are quite devoid of any odour—hence the name. A native of the Orient.

H. KALMIANUM.—At the present time this species is very rare in gardens, most of the plants

so-called being really *H. prolificum*. In general appearance the two are similar, but they can be distinguished by the present species having five styles and five divisions in the seed-vessel, whereas in *H. prolificum* there are but three. It was discovered by the Swedish, botanist, Kalm, probably at Niagara Falls, which he visited in 1750. It had reached this country by 1759. Professor Sargent, who figures it in *Garden and Forest* for 1890, describes it as rather rare and confined to lake and river-cliffs from the Falls of Niagara (where it occurs on Goat Island) to the Northern Lakes. It is a bush 2 feet to 3 feet high, plentifully furnished with leaves each 1 inch to 2 inches long, and, from July to September, with bright yellow flowers each 1 inch in diameter.

H. MOSERIANUM.—So far as I know, this is the only hybrid *Hypericum* hitherto obtained in gardens. We owe it to Mons. Moser, of Versailles, who raised it some ten or twelve years ago from *H. calycinum* fertilised with the pollen of *H. patulum*. It is remarkably intermediate between the two, and may in some respects be said to be superior to both its parents. *H. patulum* is a rather tender plant, but a very graceful one, and the hybrid has inherited a good deal of its grace with some of the constitutional vigour of *calycinum*. It is, however, by no means so hardy as the latter, and whilst it has proved fairly hardy at Kew (although very frequently cut back to the ground), complaints are made of its being killed outright in the northern counties. In most parts it is advisable to give it some light covering during very hard frost. The coloured plate now issued will give the best idea of its beauty. It is a graceful low bush, whose arching or even pendulous shoots bear their numerous flowers from July to September. This year one might have gathered flowers in late October. The blossom is 2 inches or rather more in diameter and of a rich golden yellow. On the whole, it is a very free-flowering and charming plant. Mons. André has stated that an identical plant has been obtained by M. Moser by reversing the cross. The variety *tricolor* is a variegated form, but is of no value as a hardy plant, being more weakly and tender than the green-leaved one. It has been recommended as an ornamental greenhouse plant.

H. OLYMPICUM owes its name to having been originally brought from the Bithynian Mount Olympus, where seeds were gathered and sent to the Oxford Botanic Garden by Sir George Wheeler. This was early in the eighteenth century. A figure of it was published in *THE GARDEN* for April 2, 1887. Its flowers are each from 1 inch to 2 inches across, the petals being narrower than ordinary and somewhat wedge-shaped. The foliage is glaucous. It is only hardy enough to withstand our mildest winters.

H. PATULUM.—Were it not for its want of hardiness there would be few more desirable *Hypericums* than this. It is almost always killed to the ground at Kew in winter, and in some seasons is so much injured as to be beyond recovery. But seen at its best it is a graceful and beautiful shrub. This may be seen by a plate in *THE GARDEN* for September 22, 1877. It has slender arching stems, which grow about $1\frac{1}{2}$ feet high during the summer, and its bright yellow flowers are each about 2 inches across. It comes into flower in July and continues for two months. It is a native of Northern India, China, and Japan, and although discovered by Thunberg 120 years ago, was first introduced to Kew by Richard Oldham from Japan about 1862.

H. PROLIFICUM.—Of the American *Hypericums*, this is in English gardens the healthiest, and on the whole most satisfactory (although *H. aureum* is at its best more beautiful), in consequence of which it has always been the commonest. It makes a handsome bush of erect, compact growth, 3 feet in height, well furnished with rather glossy dark green leaves that are each 1 inch to 2 inches long, and which vary in width from one-eighth of an inch to half an inch. Its clusters of blossoms are freely borne towards the ends of the shoots from July to September, each flower being 1 inch

to $1\frac{1}{2}$ inches across and bright yellow. In mild winters the plants retain most of their foliage. It seeds very freely and is weakened thereby; therefore all the pods that are not needed should be removed after the flowering season is over. The species is a native of the Eastern and Central United States, and has been known in cultivation since 1758.

H. URALUM.—Nearly allied to *H. patulum*, this species is not quite so ornamental a shrub. It is, perhaps, slightly hardier, but is still one of the more tender sorts. It grows 2 feet to 3 feet high and has leaves each 1 inch to $1\frac{1}{2}$ inches long. The flowers are produced in terminal clusters of three to twelve flowers, each bloom 1 inch across and golden yellow. It was discovered by Dr. Francis Hamilton, and was introduced in 1823. It has no connection (as might be supposed from the name) with the Ural Mountains or province; it comes from Nepal, and the specific name is an adaptation of the native name—"Urala Swa."

Arboretum, Kew.

W. J. BEAN.

THE WEEK'S WORK.

KITCHEN GARDEN.

FORCING SEAKALE.—This has been the worst season I have experienced as regards the growth of the first forced supplies, the heads being poor in comparison to the size of crown and roots. There will now be a better return, as the roots, having had a longer rest, will force easily. It will be found that forcing in a low temperature will give the best quality. Roots will now force freely in a temperature of 60° or less if a little more warmth can be given at the roots. Lack of moisture during the forcing will not be good for the plants. To forward batches of the roots for certain dates I find it advisable to water freely with tepid water early in the day, leaving uncovered for a short time for the tops to dry. If a little salt is added to the water it improves the flavour of the Kale. It will now be advisable to put roots into heat once a fortnight in quantities sufficient for the demand, and anyone who has not got a Mushroom house to force in may get reliable supplies by using boxes placed over hot-water pipes, covering the tops well and giving plenty of moisture.

SEAKALE FORCED IN OPEN GROUND.—The best quality Kale is secured from roots forced in their growing quarters. Now is a good time to cover the stools. Of course, thus early it will be advisable to have a strong plant. The chief point in culture is to avoid using too much rank manure, as this causes so much steam that the tender growths are burnt and decay rapidly. It is far better to use more heating materials with less heat, such as a goodly portion of leaves, as a temperature of 60° to 70° will be ample for the roots. Pots with covers are usually employed, but shift may be made with boxes or barrels, or even sticks placed over the crowns brought to a point and sufficiently high to allow the new growth room to develop. If the heating material is placed more thickly at one end of the row than the other, there will be a longer supply. Kale grown thus is most useful, as it does not all come in at once like that in a heated house, and the produce is much more succulent.

SEAKALE FOR SPRING SUPPLIES.—Many may think Seakale is not needed in March and April, but I find it most useful at the season named, as there are then none too many green vegetables. The best way is to grow plants specially for this work. I plant in rows, allowing 4 feet between the rows. These plants remain two years in their growing quarters. Of course they would give a much longer supply, but the produce is inferior to that from younger plants, the roots splitting up badly as they get older and are not covered so readily. I have, to secure a catch crop, planted strong crowns of roots intended for forcing, and got good results, but here the plants will not make such fine growths. Anyone who needs a spring supply may follow out this plan,

planting now if the weather is open. Though the plants may not need more than 2 feet of room the first season between the rows, they will the next. Then every other row may be lifted and forced. That for the spring supply will not need any protection such as advised for plants forced. With ample soil coverings I have had it well into May. At this season the quarter must be cleared of old leafage, and I find it necessary to place a good covering of fine ashes over the crowns, as in severe weather large birds will attack them, and in a mild time slugs are most destructive. For March supplies it is well to cover at the end of this month. I place boards about 6 inches clear on each side of the roots. This space is filled in with fine soil or ashes, and over this and the boards also, to the width of 2 feet and nearly as much in depth, is placed soil from between the rows. For later supplies I do not cover till January, and do not even use boards, merely banking up the soil over the roots, but in sufficient depth to retard the growths and also to bleach it, as in the spring it will soon push through the soil. Many growers would find it advantageous to leave a portion of their roots in the ground to be grown as advised. The quality of the produce grown thus is excellent.

ASPARAGUS.—This has forced much better than Seakale and in a shorter time than usual. Of course, much depends upon the strength of the plant as regards successful forcing. It will now be advisable to lift plants every three weeks to maintain a supply, and, unlike Seakale, it needs a light place to green the tops as they push through. I prefer a pit for supplies from now to the end of January, as there sufficient warmth may be given the roots; at the same time the top temperature, if not more than 60°, will promote a more succulent growth. Leaves and manure mixed are the safest heating materials, as manure alone is too quick and some of the roots fail to throw up. It is always a safe plan to have the heat 10° to 15° higher than that of the house or frame. Asparagus will now force without bottom-heat if placed in a warm frame or house, but the growth will be slow and not so certain. I referred some weeks ago to the importance of forcing permanent beds, and now is the time to prepare the materials and get out the old forcing material. For beds forced thus, a good dressing of fish manure or guano will do good before covering the beds if given in wet weather.

FORCING FRENCH BEANS.—This is not a profitable vegetable by any means forced in what may be termed midwinter. Unless the demand must be met, I would not advise sowing seeds till early in the year. On the other hand, with more attention to cultural details and the use of small pots, a small supply may be secured in February. For this early supply I find Early Favourite one of the best. The older Mohawk runs it closely for time, but lacks weight of crop. The usual mode of sowing in 7-inch or 8-inch pots is not advisable for first crop, as the root space is too great. Good results will follow if sown in 5-inch or 6-inch pots, and these will need bottom-heat from the start. Mine are plunged in fibre over the return pipes in a warm pit. A light compost and ample drainage are a necessity. Avoid crowding the plants; three to four plants in each pot are ample; indeed, two will suffice if strong and in the size of pot advised. It is best to sow in the fruiting pots, filling the pots nearly to the rim, as later top-dressing is of no value at this season of the year. Moisture must be given sparingly from the start, and it is important to use seed of this season's growth, such seed being more vigorous. Grow as near the light as possible and in a temperature of 65° to 75°.

CUCUMBERS.—Like French Beans, these are not a profitable crop in the winter months, but I must have Cucumbers all the year round. The winter plants are now allowed to fruit very sparingly, and they are also given more warmth at the roots. Being in pots, this is an easy matter. All surface roots should be encouraged, for as long as these are made there will be a

certain amount of top growth, and this should be made the most of, only one fruit being allowed at each joint at a time. Avoid strong fumigation, as this tells on the tender foliage, and the plants soon fail if the foliage is poor. If at all troubled with red spider or thrips use the N. E. All vapouriser, which is safe and effectual. Plants with a fair lot of fruit should never be allowed to carry it a day longer than is necessary, as the fruits when cut will keep a goodly time in water and be none the worse. I find it advisable to top-dress the plants every three weeks, using a rich compost, such as bone-meal and good loam, with a portion of spent Mushroom manure. The temperature should be a liberal one, 65° at night, 5 to 10° higher by day in bright weather, covering the glass at night to prevent hard firing. Water always with tepid water or liquid manure. Seeds may now be sown for planting out early in the year. These will fruit late in February.

TOMATOES.—Plants with fruits ripening will now need more warmth with at the same time ample ventilation in bright weather. I have this season, owing to the damp weather of late, had more fruits crack than usual. Warmth will not do much good unless the plants have finished cropping, as too much heat breeds white-fly and causes a spindly growth, and any small fruits set fail to swell. Plants raised in August or earlier are still on shelves in a temperature of 55°, and as long as the mild weather lasts they will remain thus. Towards the end of the month the first lot of young plants will be placed in their fruiting quarters, and with lengthening days more warmth will be given. Now is a good time to sow seeds for early spring fruiting. I have found sowing two or three seeds in a 3-inch pot a good plan for a very early lot, as the two weakest seedlings can be destroyed, and the plant left does not suffer in the least. S. M.

HARDY FRUIT.

OLD GARDEN WALLS.—From the point of attractiveness there is a beauty all its own in old walls, even if the bricks or stones composing them are crumbling down or the mortar falling out. But from the utilitarian point of view it is not so; old walls often give to those in charge of them a considerable amount of trouble. This will arise from two (at least) various sources. Rotten or crumbling walls are bad for the operation of nailing, owing to which those who have this work to do cannot be blamed if they do drive nails into the brickwork where it is sound. Another and more serious argument against them is the protection they afford to insect pests. Of these there are the wood-louse and the earwig, both of which will commit serious depredations upon tender fruits in the autumn. The former enemy is very fond of the best kinds of Plums and will mark these if they happen to touch the wall. The earwig preys upon Peaches and Nectarines to a serious extent. These old walls afford to these insects a safe retreat. Then there are aphides in variety, with other troublesome things as well. It is, I am aware, a somewhat expensive process to point a wall of considerable extent, but, all the same, it is a matter that calls for attention. If taken in time it will prevent the bricks from crumbling away also, which otherwise is likely to occur during severe frosts. When repointing is done, it is worth while to consider the question of inserting studs in order to save so much, if not all, the nailing. Stud driven into the joints of the brickwork will answer well for securing the old wood if for nothing beyond that. These studs should be driven home so as to keep the trees as close to the wall as possible. If placed at regular intervals and so arranged as to insert a good quality of tarred string in a diagonal form, a deal of nailing may be saved and the walls too. The present season of the year is the best for doing this work, better by far than the spring-time when the buds are swelling. Then there is not only the prospect of injury to these, but it also means a delay in attending to the trees. In most cases, good mortar made of fresh

lime and sharp sand will answer the purpose well, being less expensive than cement, and, on the whole, far more expeditiously applied. At such times the top-course of these walls should be repaired too, otherwise, if the wet gets into them, further injury will be done. Do not omit either to clear away the surface soil, so as to give attention to these courses as well. If projecting tiles are arranged at the top, see that they are kept in good order too. Should it be intended to provide glass copings for the walls, it is most advisable to get the work forward as expeditiously as possible so as to have the full benefit of them next spring. Where these already exist, see that all the iron fixings are secure, also that the glass is sound.

RENOVATING OLD TREES.—Some growers may have to do with old trees of good varieties, be it Apples, Pears, Plums, Cherries, Peaches, or Nectarines. These may be established favourites which are not parted with readily, but which are showing indications, perhaps, of declining vigour. If such be taken in time, it is frequently possible to rejuvenate them for some years to come. The best restorer undoubtedly is good maiden loam with a moderate amount of well-rotted farmyard manure, to which is recommended also a fair dressing of bone-meal or lime rubble, especially for stone fruits. Exhaustion in the case of these may be only from want of phosphates in the soil. If this be so, then omit the farmyard manure and make more use of those named afterwards, but not in an excessive degree, otherwise the very object will be defeated. It is always possible to gauge pretty accurately as to what is wanting. If the growth be weakly it indicates a want that will be supplied by all that has been recommended, but if it be of a non-fertile character with vigour of growth present in the trees, it points to a deficiency in the constituents of the soil for the complete development of the fruit; hence the use of lime in varied forms when the soil is non-calcareous. The old soil should be carefully removed until the roots are reached, when if these are found to be at a great distance from home they may be pruned, some if possible being lifted so as to work the fresh loam amongst them. If the case is not a really bad one and the fresh loam not conveniently at hand, a surface dressing of bone-meal should be forked in and then a mulching of farmyard manure applied. In the case of many trees this has been found to be beneficial after a season or two. Trees on grass do not, as a rule, get any manure, and they go on from year to year, but it would be better for them if occasionally the ground were broken up. If this be done the turf itself can be buried, and this of itself will be a manure, but in addition the others, as just recommended, should be added. If not supplied with what they need many old trees will become quite worthless. They might possibly develop flowers, but not be able to carry a crop of fruit to completion in a satisfactory manner. Upon heavy soils the growth may be vigorous still upon aged trees. If these are bearing fairly good crops on the whole, but the fruit small, it points again to the need of assistance. In such cases let it be of an artificial manure in which nitrogen and ammonia, two excitable manures, do not predominate over phosphates and potash. Old orchard trees often need a careful amount of pruning even if they are still in good bearing condition. The wood must of necessity become too dense in course of time. To remedy this, the innermost, which will also be the weakly branches, should be thinned out. These shaded growths cannot be productive of good fruit under any conditions. Occasionally an outer branch may be growing too strongly and be spoiling the balance of the tree; any such should be foreshortened, but not to an excessive degree all at once. See that all cuts are made clean and also close up to other branches in order to avoid any after-decay taking place. HORTUS.

Primula floribunda.—This pretty species is undoubtedly well named, for scarcely any other

kind, save perhaps the better-known *P. obconica*, possesses a more profuse habit of flowering than this. The individual blossoms are, it is true, rather small, but this is compensated for both by the numbers and the rapid succession in which they are produced. In the colour of the flowers, however, the plant occupies a position almost unique, the only other yellow-flowered species being an Abyssinian kind of about equal hardiness. This latter, however, is not so profuse, but by attempting a cross between the two, size of flowers on the one hand and a greater profusion of flowering on the other may be secured. *P. verticillata*, the other kind referred to, possesses a very attractive habit of growth, and being, like the above, a free seeding kind and of easy culture also, the experiment here suggested should be tried, as a break once gained between any two species in this way can soon be improved by seeding and selection.

CHRYSANTHEMUMS.

CHRYSANTHEMUMS IN DEVON.

CHRYSANTHEMUMS were brilliant in the gardens during the early part of November, and even the slight frosts which occurred later and the heavy rains did not entirely terminate their display. This is the second year in succession that open weather in October and November has made the culture of midseason Chrysanthemums under glass unremunerative, for with a wealth of the same flowers and Dahlias blooming in the open, purchasers of the blooms of housed Chrysanthemums were few and far between. This season the early varieties were, at least in this neighbourhood, later than usual, while varieties generally classed as late bloomers matured their blossoms in advance of their accustomed time. Thus *Niveum*, which when lifted from the open ground and planted out under glass produces excellently developed flowers for cutting, almost equally as good, indeed, as those on pot plants, was at its best towards the end of November, although the plants had only been housed at the beginning of the month, whereas in 1896 it was in full beauty on Christmas Day. Its yellow sport, which, though perhaps of rather too light a colour, inherits the full-petalled blossoms that make its parent so desirable an acquisition, matured its flowers at the same time. Many blooms of *Princess of Teck* are already past their prime, while *Ethel*, a poor variety for cutting owing to its open dark eye, and whose demerits are intensified when the plants are lifted just preparatory to flower expansion, is already ripe for the knife. *L'Enfant des deux Mondes*, with its spidery, feathered petals, provides graceful sprays of flowers under the method of culture alluded to, but will be too far gone for cutting in the course of another week. *Princess Blanche*, sent out as a late variety, is already past its best, but *Princess Victoria* is not as yet fully expanded, and should keep for another fortnight or three weeks. This variety as well as *L. Canning* are apparently the two best late whites for fitting from the open and planting out under glass, as both are in excellent health and are producing full-petalled flowers freely. *L. Canning* will probably reach perfection about Christmas-tide, but the old *Boule de Neige*, last year a Christmas flower, is at the present date ripe for cutting. Of yellows, *W. H. Lincoln* does not lend itself to this method of culture, losing much of its vitality. Plants of this variety that were carefully lifted from the open early in October are, however, looking well. *Mrs. J. F. Fogg* is a good, rich yellow that lends itself readily to the lifting and housing process, as does another

bright yellow, *E. J. Hill*, with the reverse of its outside petals orange-red. *Tuxedo* is precisely similar to the latter variety in habit of growth and in the colour of its expanding buds, the open flowers, however, being of an orange-buff, whereas no tint but yellow appears in the expanded blooms of *E. J. Hill*. Another good yellow for cutting is the so-called single *Admiral Sir Thomas Symonds*, which lasts well. All of those named are at the present time so far advanced, that there is little prospect of any of their blossoms being available at Christmas. Of dark colours, *Cullingfordi* and the old favourite *Julie Lagravere* have already passed the zenith of their attractiveness, but the orange-crimson *W. H. Coles* still carries blooms not fully expanded. The old-fashioned *Roseum superbum*, with its delicately coloured blooms of blended pink and saffron, is a particularly decorative variety, but was at its best this year in mid-November. S. W. F.

Topazay.

INCURVED CHRYSANTHEMUMS.

NOT for several seasons past have the incurved Chrysanthemums been seen in such fine form as at the many exhibitions this year. Outside the chief London show they have appeared the best, and in several cases a dozen or more competitors were found in a class. That perfect type, of which *Lord Alester* is, perhaps, the leading one, known commonly as the "Queens," was not generally abundant, but in a few instances was particularly good. The improvement seems more notable in the newer introductions, which are not so difficult to cultivate as are those of the type named. It was a step in the right direction to allow the more loosely built incurving forms into what was hitherto a very limited class, and this fact more than anything else has been the cause of renewed interest in incurved Chrysanthemums. This class a year or two back looked like being entirely ousted by the popular Japanese kinds, a fate which has overtaken the reflexed, *Anemones*, and other divisions.

Speaking of the newer varieties of incurved, nothing finer, for example, than the half dozen blooms of *Duchess of Fife* that won first prize at the Aquarium, Westminster, in November has been seen for some time. Next to it is *Chas. H. Curtis*, a sort that can be cultivated well by everyone. *Ma Perfection* and *Mme. Ferlat* are two white blooms of large size and good form. These, again, are easily grown. Except in a few cases, *Lady Isabel*, bluish colour, was not in good form; generally very large, but coarse. I am afraid one requires a goodly number of plants of it to obtain a good specimen. *Topaze Orientale*, a creamy white flower, is large and capitably formed. This is altogether excellent, as its growth is dwarf and sturdy. *Yvonne Desblanc* is a nice pure white flower, the florets of good shape and incurving evenly. *Globe d'Or* is fairly well known now, and is a telling bronzy flower of easy culture. The blooms of *Rena Dula* are not over large, but they are especially neat, whilst the colour—rosy lilac—is bright and pleasing. *Miss V. Foster* was seen good. With me, however, it is a tall grower and uncertain to bloom. Nor is *Miss Dorothy Foster* much better, although the habit of the plant is good and the colour a deep lilac, somewhat like that of the last named. *Bonnie Dundee* is seen in Kent a very rich bronze bloom and of capital form, but this is not the case everywhere. *Mrs. R. C. Kingston*, when in its true colour a richly tinted white, is a remarkably good incurved sort. The white *Mlle. Lucie Faure* comes with blooms more often of a Japanese shape than a true incurved. In any form it is a striking flower, and one that should be largely grown. Promising among the newer kinds of the class under notice are *Mrs. S. Owen*, brown tint; *Mrs. W. C. Egan*, pink; *Pearl Palace*, shaded white; and *Rose Owen*, pink. Several new ones have obtained certificates this autumn, and

they are certainly likely to prove first-rate additions. *Mrs. W. Howe*, bright yellow; *Miss Annie Hills*, bluish; *Hanwell Glory*, bronze; and *John Mills* are all of fine form and size.

Brighter and darker colours are much needed among the incurved class. *Austin Cannell*, a purple shade, is usually rough in form. The old variety *Refulgens* is seldom seen now, but in crimson nothing new approaches it. It is, however, the way of Chrysanthemums to exhibit the deeper shade inside the florets, and not until that order can be reversed can we hope to have shades of deep red in the incurved forms.—H. S.

—Although the Japanese kinds predominate, there is, I think, more interest among a certain class of growers in anything new or striking that is discovered among the incurved. During the present season several novelties of recent introduction, that promise to be useful in the future, either on account of their size or colour, have been met with. Most of those mentioned below are deeply built, compact, and very regularly incurved, qualities of paramount importance to the grower for show. *Thomas Singleton* is very closely incurving and a compactly built flower, pure white, the outer florets tinted. *C. S. Bates* is a deeply built, very regular flower, large in size and of a pure golden chrome-yellow. *Pearl Palace* is a rather promising variety, colour pinkish lilac, and another is called *Mrs. W. C. Egan*, very deep and solid, colour pink. All these were seen in the collection of *Mr. Owen* at Maidenhead, and will presumably be distributed next year.

Among other novelties of the incurved section, some of which were seen in very good form last year, are the following: *Miss Godsmah*, with very fine deeply-built blooms, compact, but rather coarse, inside of florets crimson, reverse golden bronze; *Ada Owen*, very pretty and regular, large in size, having stiff florets, which are close and compact and rather broad, colour pure white. *Major Matthew*, a rather pretty little flower, has narrow florets, of good depth, globular in form, colour pink. *Yvonne Desblanc* is a very large pure white; so, too, is *Topaze Orientale*, very deep in build and with numerous closely incurving florets, colour pale yellow. *Emile Nonin* is somewhat flatter, but of value on account of its colour, which is a deep golden chestnut. *T. Lockie* is something in the way of *Mrs. R. C. Kingston*, close in build and with very regular narrow, white, tinted yellow outer florets, shaded pink. *John Miles* is another whose build leaves little or nothing to be desired, colour golden orange bronze.—C. P.

Late Chrysanthemums.—Seldom has there been such a wealth of bloom on outdoor Chrysanthemums as during the present year; in fact, they have so completely glutted the markets, that those grown under glass have been a dead letter as regards any profit. Now that frost has brought outdoor blooms to an end, we may look to late blooms under glass to be of more value. In looking over my stock, I have come to the conclusion that Chrysanthemums for late blooming are propagated much too early in the year, for I find that one of my best lots of dwarf bush plants of *W. H. Lincoln*, yellow, was not propagated until May, when a good many of the others were ready to go into their flowering pots. The cuttings in question were good sturdy tops and were placed singly in 2-inch pots, where they very soon rooted sufficiently to be transferred to 4-inch ones, when they were set out in the open with the early ones and stopped at the end of June when they had developed several side shoots. As soon as they began to grow again they were shifted into 6-inch pots, and have each about a dozen good heads of bloom. Late propagating and late cutting back of the plants are far more efficacious in getting late bloom than any attempt to retard plants that have perfected their growth early in the season. When once the plants are placed under glass the flowers will naturally continue to expand, and once fully open, there must be warmth enough to expel the damp, so that retarding them in mild, wet weather is by no means easy. If the buds are firmly rolled up at the end of November, as they

will be on late-struck plants, good blooms for the new year will be assured.—J. G., *Gosport*.

CHRYSANTHEMUMS IN RUSSIA.

I would be greatly obliged if some Chrysanthemum grower would give me the names of the best large-flowered Chrysanthemums, new or old. They ought to be rather dwarf, not too late (October, November), and of easy culture. Of the kinds I grow, I like best Bouquet des Dames and its yellow sport Germania, Ma Perfection (rather small, but of exquisite form and growth), Robert Powell (rather tall), C. Shrimpton, Avalanche, W. H. Lincoln, Florence Davis, Ch. Davis, Vivand Morel, Wm. Trieker, G. C. Schwabo (splendid), Mrs. E. J. Trafford, Louise (fine), Souv. de Petite Ami, Mme. Ad. Chatonay, John Shrimpton, Mme. M. Ricoud (rather tall), Soleil d'Octobre, Mme. G. Henry, Lady Hanham, and Duchess of Wellington. I find the following good: President Borel, Pride of Madford (rather tall and somewhat late), Emily Silsbury and W. Seward (both rather weak stalks), Duchess of York (rather tall), M. Chonon de Léché, Mrs. C. E. Shea (tall), Mutual Friend, Stanstead White (rather uncertain and tall), Etoile de Lyon (coarse), G. W. Childs, and Niveum. I intend discarding La Triomphante, Sir Edwin Smith, Rose Wynne, Edith Tabor (splendid bloom, but growth too tall), Miss Storer, E. Audiguier, Puritan (too small), Mrs. T. S. Fogg, Amy Chandler, Amiral Avellan, Deuil de J. Ferry, Commandant Blusset (the form as well as the colour is not very interesting), Mme. Carnot (too uncertain), M. Chas. Molin, and Mrs. A. J. Hubback. Some of the following have not yet flowered; the remainder flowered only once, so that I cannot judge them: Good Gracious, Phebus, Amiral Kasnakoff, Miss Dorothea Shen, Mrs. J. Shrimpton, M. Pankoucke, Mrs. H. B. Higgins, Mlle. Lucie Faure, Khama, Antoinette, M. Edouard André, Mme. Ed. Roger, Mme. Ernest Capitain, Miss E. Teichmann, Mrs. T. Lewis (seems to be very tall), Western King, N.C.S. Jubilee, Ch. H. Curtis, Modesto, Hairy Wonder, Fleur Grenobloise, and Chatsworth.

I should be very glad to get your advice as to which of these kinds I can discard. I hope to hear of some other fine sorts which I could add to my collection, which contains chiefly light-coloured kinds. In the purple or amaranth class I have Edouard Audiguier, Commandant Blusset, and Pride of Madford. The oldest of this trio is, of course, Edouard Audiguier, and I thought of discarding it some three or four years ago. Its place should be taken by Commandant Blusset, but I intend to discard both of them. Pride of Madford is the best of these varieties, but I am not quite satisfied with it as it grows rather tall and flowers rather late. Is there no better variety of this colour? I think J. Shrimpton the best all-round variety, as it is very easily grown, but its form is very flat. Better in form and also in colour is W. Seward, but this variety is not easy to grow, at least not with me. Grown in the natural way (I mean without pinching, and after the first break three or four shoots taken up and the first bud secured) it gets rather tall and leggy. The stalks being rather weak cannot support the blooms. The blooms attain a good size, but they are apt to damp. If the plants are pinched twice the blooms do not damp, but they open too late and the flowers do not reach a good size. Vivand Morel behaves with me rather in the same way as W. Seward. Pinched once it blooms early, the colour almost white, and a good percentage of the blooms will not open well: pinched twice, the blooms open well, the colour is good, but the flowers are somewhat small. Most of the large-flowered Chrysanthemums are propagated about the end of January or beginning of February.

I was very interested in the article, "Growing Plants for Exhibition" (p. 316). As I understand, the plants are to be propagated rather late—beginning of March—grown on without any pinching and the first bud taken. Would rather

early kinds like Lady Hanham, Vivand Morel, Ch. Davis, W. Seward, and others grown in this way yield satisfactory results? I should think that such sorts would shew the bud too early, and consequently give bad results. What are the principal merits of Princess, Queen of the Earlies and Mychett White? I have grown these kinds this season for the first time and I could not see anything beautiful in them. Is it better to disbud them? R. K.

St. Petersburg.

TESTING CHRYSANTHEMUMS.

Of the well-nigh endless lists of novelties in Chrysanthemums that are each year offered to the public but a fraction of them is ever thoroughly tested to see the flowering capabilities of individual kinds. Indeed, it seems impossible that it can be otherwise seeing the influx is so great. So far as the exhibitor is concerned, a few novelties are selected each year in greater or less degree according to the amount of enthusiasm prevailing in a certain direction. These few are, of course, grown for a special purpose, and the chances are if they do not come up to expectations are discarded without further ado. If the variety is a tall one, it is more than likely the second crown bud will be chosen for flowering, and if a very dwarf grower the terminal may be the one selected. Beyond testing on the buds named little or nothing is known of scores—aye, hundreds of kinds, that have been sent out with the most lavish descriptions attached to their names. It frequently happens that some kinds absolutely refuse under certain conditions to perfect good flowers, while others selected, it may be, from this bud or that, stubbornly refuse to move. Naturally enough from an exhibitor's point of view these latter are the earliest to be discarded outright. All the same, it is possible were a more natural system of flowering indulged in, and, say about one-half of the attention and feeding given as when grown for exhibition, the same variety would perfect a dozen very respectable and useful flowers. This I have proved over and over again. It seems unnatural, too, that a specially vigorous kind, and a good vigorous rooter withal, can find vent for its energy and vigour in the production, say, of one, two, or, it may be, three blooms. Elaine, a kind well known to gardeners, to exhibitors, and to market men also, will illustrate what I mean. This variety, still the purest white in existence, I believe, when only allowed to carry a few blooms on early crown buds, is a short-petalled, stiff, balled-up sort of bloom that in these days of grace and refinement is little short of repulsive. The same kind when allowed to mature from eight to ten flowers on terminals is one of the most graceful and elegant. Indeed, it not infrequently happens that the most elegant flowers are those from terminal buds. Another well-known white, Souvenir de Petite Ami, is liable to do the same thing, the crown flowers short, stubby, and ugly-looking when the plants carry about three blooms, and most pleasing and beautiful when the plants are allowed a maximum of nine blooms per plant. These, of course, are not the huge exhibition blooms we see so much of, but such as would be 3 inches or 4 inches deep in petal and about 5 inches or 6 inches in diameter, blooms large enough for all purposes of decoration, and such as may be cut with 12 inches or 20 inches of good stem. In growing this variety so, care should be taken not to overcrop, because the shape of the bloom causes the eye to be seen in the centre. This, however, may be regulated by the individual vigour of the plant, and it is a poor one indeed that will not carry half a dozen very fine blooms. Were this item mere fully realised and acted upon, it would be the saving of much time and labour in raising and growing stock to produce a sufficient supply of bloom. There are doubtless many others that could be named. In yellows the well-known W. H. Lincoln is wonderfully prolific, yet I lost a season when this plant was first sent out through seeing a plant exhi-

bited with a single stem and a solitary bloom on the top. My two first plants of this fine yellow carried respectively forty and forty-eight fine blooms each. It must be stated, however, that the one pot had two and the other three cuttings in, but, being rather late, were potted on in this way and flowered in large 8-inch pots. The plants were never stopped, and spread out into bushes nearly 3 feet through, and with attention produced highly creditable flowers. The variety of W. H. Lincoln called "improved," unfortunately re-christened and re-distributed as Wm. Slogrove, is another good free kind, though scarcely the equal of the original, and, of course, differing in the shade of yellow. Doubtless there are dozens more only waiting to be found out, equally good and equally free and prolific, quite apart from those recognised as "decorative." The curious part is that these kinds do not show a proportionate increase in size when the blooms are limited to three. This is well-known in some decorative kinds, and, of course, equally true here. What I find a good guide to work upon is the kinds that are most stubborn on the early crown buds. These not infrequently perfect a fine lot of blooms when allowed a free and almost unrestricted growth. E. J.

STRIKING CHRYSANTHEMUM CUTTINGS.

ROOTING: cuttings for another year will soon be in full swing, and the object of this note is to question the mode of procedure pretty generally adopted. I mean putting the cuttings singly into small pots, and afterwards placing them in frames within the greenhouse. This plan has been the cause of a number of failures, especially among amateurs, inasmuch as the little attentions, such as removing damp from the glass regularly, have been neglected and decay of the cuttings has resulted. At the best it is a coddling practice, and often the little plants receive a check when taken from a closed box to inure them to air. It is also a tedious plan, many sorts being about six weeks in rooting. The soil by that time is sour, which causes still further delay in the young plant growing away freely. A first-rate mode is to prepare a shallow bed of light sandy earth in a frame, or, better still, a heated pit where warmth may be obtained if necessary, and dibble the cuttings in about 3 inches apart. Failures are rare with this treatment, and air may be given to produce short, sturdy growth. The trade growers' system of striking the cuttings in shallow boxes has, to my mind, the most to recommend it. Boxes about 18 inches long, 12 inches wide, and 3 inches deep are used. These are filled with suitable soil, the cuttings put in, and a good watering given to settle the earth. They are then placed in any glass structure and frost kept away, the houses in favourable weather being only partially closed. No shading is employed, the leaves therefore flag slightly, but a sprinkling with water prevents undue evaporation, and after callusing, the cuttings begin to pick up, and finally emit roots without having made any apparent top growth. The boxes, being so convenient in size, are then stood on shelves near the glass, where air and light assist stocky development. After all, the quickest mode appears to me the best, and one by this plan may root most kinds under the month during winter. Sorts late in giving cuttings or slow-rooting ones may be placed in a warm temperature, and if removed before the leaves become drawn, make satisfactory progress afterwards. H. S.

Chrysanthemum Mrs. Barkley.—Mr. Weeks has produced no variety of more distinctive character than is this exceedingly fine reflexed. I hesitate to class it as Japanese, although presumably it is such, because its form is so much more like that of the old reflexed Cullingfordi. The petals are, if short, at least very broad and flat, and they lie out regularly and effectively one over the other. We have had so far no Japanese showing this fine reflexed form

without presenting also a good deal of curl in the petals. The form of the flower is nearest furnished in good early blooms of *Chenon de Léché*, but that is far from being so good a reflexed variety. Would it not be a gain if through Mrs. Barkley and doubtless others of similar form, though diverse in colour, it might become possible to get back the once favoured show section of *Chrysanthemums*, such as Dr. Sharpe, King of Crimsons, Cullingfordi, Chevalier Domage and others, all charming varieties, but elbowed out of existence in the craze for huge flowers? Now Mrs. Barkley gives size as well as form, very possibly it may not be difficult to find even now amongst the myriads of Japanese in commerce a selection of varieties that could be shown as reflexed if a class were established for them anywhere. Certainly all incurved flowers, whether Japanese or not, should be exhibited in the incurved classes, and with these deductions there would still be a myriad of diversely formed flowers to make up the ordinary Japanese section.—A. D.

FLOWER GARDEN.

ERIANTHUS RAVENNÆ.

THIS is a native of Southern Europe, which will tell us that a little straw or leaves as protection during the winter months is desirable, although not exactly necessary if it is planted in a sheltered position. It should be given the full benefit of the sun and thrives best in a well-manured sandy or gravelly soil with plenty of moisture. Planted at the margin of the shrubbery, in the hardy plant border or edging the Lily ponds, its bold form is pleasing, and especially in the autumn do the feathery plumes, carried on strong stalks and waving slightly in the breeze, give life to the surrounding landscape.

Compared with other ornamental grasses, it is equalled only by the Pampas Grass (*Gynerium argenteum*), which, unfortunately, is not hardy in this latitude. Under good cultivation, *Erianthus Ravenne* will attain a height of 10 feet or more. It comes into bloom the first week in September, which is an advantage, as most of our ornamental grasses do not produce their feathery blooms till late in the season, to be enjoyed for only a short time. The illustration shows a clump of twelve plants put out a year ago.—JAS. JENSEN, *Illinois, in American Florist*.

Begonias in the flower garden.—Few things have made greater strides of late years than Begonias, and they certainly aid greatly in keeping the flower garden bright for several months in the year. Moreover, the blooms are not easily damaged by wet; indeed, the plants seem to flower more freely and do better altogether in a dripping season. Begonias like a rich, moist larder; therefore the beds should be well prepared in early spring by a liberal addition of well-rotted manure. After digging deeply, a little artificial manure sprinkled on the surface and raked in will assist the roots when the plants are first put out. It is important that the plants be brought on as gently and coolly as possible in spring, so as to secure a hardy, stocky growth. Summer mulching is important for the preservation of moisture in the beds, and also to prevent the soil from being washed away from the bulbs by the frequent and copious soakings needful if the season is hot and dry.—NONWICH.

Himalayan plants. A great many of these have been introduced to our gardens, but more yet remain apparently which are equally suited to our climate. In Sir J. Hooker's Himalayan journals, abridged edition, vol. ii., p. 65, appears the following: "A great red Rose, one of the most beautiful Himalayan plants, whose single

flowers are as large as the palm of the hand, was blossoming, while golden *Potentillas* and purple *Primroses* bordered the stream." The height at which these flowers grew is not specifically mentioned, but from the contents appears to be between 8000 feet and 9000 feet. On p. 77 the flora on the Zeum River is dealt with. After mentioning the masses of *Rhododendrons*, with strains from which the travels of Sir J. Hooker have so greatly enriched our early summers, he goes on to say: "Primroses were next, both in beauty and abundance, and they were accompanied by yellow *Cowslips*, 3 feet high, purple

plants, for Mr. Wilson's "blue" *Primroses* are in reality a long way off that colour, even when in their best character.—J. J. R.

Japanese Lilies.—Up to the present at least the supply of *Lilium auratum* from Japan has been very limited, and as a matter of course considerably higher prices are realised than has been the case for some seasons past. A grand lot of bulbs of *L. longiflorum* from Japan was disposed of early in the season, since which in the London sale-rooms the different Lilies from that region have not been up to the standard of previous years. The beautiful *Lilium rubellum*, announced

Erianthus Ravenne in a garden in Illinois, U.S.A.

Polyanthuses, and pink, large-flowered dwarf kinds nestling in the rocks, and an exquisitely beautiful blue miniature species, whose blossoms sparkled like sapphires on the turf." Then *Gentians*, *Aconites* and *Fritillaries* are mentioned, with a very handsome giant *Rhubarb*. Possibly the tall "Cowslip" may be what we now grow as *P. sikkimensis*, but the other *Primulaceæ* are apparently not in cultivation. Certainly the "blue miniature" species is not. Possibly the Himalayas may yet give us a real blue in these

for distribution by thousands, does not appear to be a good traveller—at least this year—while I have not seen the grand bulbs among the consignments of the different varieties of *L. speciosum* that one is accustomed to meet with. True, we generally get some splendid Lilies after Christmas, and perhaps this season the late ones will be better than those sent earlier. Where planting has to be done late in the season, these new-year importations from Japan have much to recommend them, for even as late as March the

bulbs are quite firm and in every way in good condition, so that if planted or potted then they can be depended upon to flower well. At the same time, home-grown bulbs will be by the period named in full growth.—H. P.

Single Violets.—I am afraid that not only Violets of the Marie Lonise and Neapolitan section, but also the single varieties will have suffered very much through the drought of the past summer, especially where grown in large quantities and receiving only rough-and-ready attention. I shall not be surprised to hear that the produce from open fields is very poor next spring. The new California resists red spider better than most varieties on account of its more vigorous foliage, but no single any more than double variety will escape its ravages in hot, dry seasons unless planted where water can be given and the foliage hosed. The worst of spider-infested plants is that in addition to a poor crop of flowers the runners for next year's planting get infested, and so a bad start is made. I have found single Violets do best for an early crop of bloom in cool brick pits. The plants should stand sufficiently far apart to allow of the runners being pegged into the soil to root some few weeks before being planted out.—N.

THE ADORNMENT OF FOUNTAINS, STREAMS AND POOLS.

THE landscape style, drawing its inspiration from beautiful natural scenes, has in the water an indispensable ornament to its artificial creations which present in harmony of the happiest kind for the mind and the eye natural pictures the most diversified. To combine, in fact, the aspect of a wood, a wooded hillside, a grassy valley, natural rocks, flower parterres, and not to associate with these the stream meandering among the verdure of the fields, the pool slumbering in the plain, the murmuring stream and the noisy waterfall would be to make an incomplete picture to which life would be wanting.

The presence of water gives life to the landscape in whatever form, from its first appearance as a rill murmuring amongst the scattered rocks or gushing forth a foaming cascade, to become further on the capricious stream of a thousand meanderings, creating everywhere in its passage miniature gulfs and tiny promontories, until the point where the nature of the place aiding it forms the tranquil sheet wherein it reposes. So it is with pleasure one loves to contemplate from the source to the pool the charming water landscapes which adorn the garden. The genius of the landscape gardener has been able to create out of a little water the most diversified scenes which these are capable of giving, and that sometimes in a prescribed space. Rocks, grottos, cascades, streams, fountains, fords, rustic bridges are to be found in all beautiful gardens at the present day, of which they are the most charming adornments.

But such water scenes would be incomplete if they did not possess vegetation peculiarly their own to adorn them in a thousand ways, with plants differing much between themselves in their form and mode of life. More than any other part Nature seems to have taken pleasure in embellishing water-places in all sorts of ways; from plants almost alpine, which grow on rocks where the stream takes its rise up to the pool, a whole world of plants disputes for a place in the liquid element. The banks are covered with Irises, Rushes, Menyanthes, dwarf Willows, Myosotis, Alisma, Lysimachia, &c., and among these Typha, Sparganium, Acorus, Ranunculus, and Butomus push more into the water to form veritable tangles there; whilst Water Lilies, white and yellow, display tranquilly their rounded leaves over the surface

of the water and their cups of alabaster or gold. But if this exuberant vegetation of water scenes is apt to excite the admiration of the poet or the painter seeking Nature in wild spots, it needs, however, a controlling hand when contributing to the adornment of places artificially created. It in effect is a question of how to adorn in the most natural way possible and with the utmost taste water scenes from which it is fitting that nothing be withdrawn of their peculiar decorative element that is to say, of the part which they play in the adornment of the garden as a whole. Landscape architecture has sought to preserve for the fountain, the stream, the pool their most natural forms; therefore is it expedient not to destroy the harmony of these forms by an exaggerated or inartistic use of aquatic vegetation. It is important also not to hide the beauty of a point of view in the landscape by using plants of too great height. To vary as much as possible, according to the importance of the site it is intended to adorn, the plant life of the water and its edges and to arrange it artistically, such is the rule to be followed in this sort of decoration. And may I be permitted to say here that the vegetation of water places is not always as complete and varied as it ought to be and might be, for very often a pool or a fountain offers no more to the view than a sheet or a riband of silver set in the emerald of the sward instead of having its surface and its margin flecked and edged with flowers.

The marginal embellishment of streams ought to be subordinate to the importance of the subject. Dwarf plants, mostly water plants, and some less spreading surface things have their places marked out in the adornment of little streams, of tiny watercourses, and their margins. Their places are found indicated in the little inlets and capes close to the fords and rustic bridges at the approaches to waterfalls. Other parts similar but more important may be a home for plants of larger size to which more room can be allowed for growth, and some floating but not very spreading species have here a place in the middle of the water, provided they be not too often repeated in the landscape. The adjacent parts of grottos, springs, and waterfalls should be little cumbered with water plants. If there should be high rocks, alpine flowers should adorn these in concert with some shrubby element of the mountains. Further on, among rocks half emerging from or level with the water, the vegetation sees a change again; plants of the marshes and of the bog are here in place together with a whole series of water kinds.

The scheme should be restricted to a few subjects in places that are only partly water; it may multiply, on the contrary, in proportion as the water occupies a larger space and affords more room for the particular plant-life of those places. Water copied from Nature—that is to say, water in all its forms, whether they be called reservoirs, ponds, pools, fish ponds, lakelets, &c.—affords to aquatic flora space for that development which is necessary to the beauty of the most spreading and most vigorous kinds. Properly combined in more restricted spaces, the plant-life may be very varied without profusion, and may include examples of every sort of amphibious species. In water of greater extent, freedom of place is given to the most diversified plants.

On the right choice of species depend all the beauty and variety of water gardening, as knowledge of their native habitats and their preferences is necessary to ensure their good growth. The adornment of any piece of water

may be carried out on the margins by means of water or floating plants, and on the water itself by means of certain surface, or really floating, species which reach their full development on the surface.

The indigenous flora of the waterside, with the addition of some exotics known to us, possesses elements the most diversified in form in plant and flower, imparting to the banks of streams and sheets of water a vegetation as varied as numerous.

But, apart from this special embellishment of water places and their margins, there is another form of adornment which must not be forgotten, which, though no part of the present subject, ought, nevertheless, to interest us, since it contributes to embellish the view of water by planting close to the waterside plants of generally picturesque aspect delighting in cool places. Trees, shrubs, herbaceous plants are used for this purpose. Their use should be governed with discretion, and their presence ought not to destroy the general harmony of the site. It is the work of the landscape gardener to place on the water's edge here the Weeping Willow, the drooping Ash; there the Tamarix and Cotoneasters, whose branches incline gracefully over the banks; Bamboos, Gunnera, Rhubarb, and Fern displaying their luxuriant vegetation on the bright green sward. Numerous are the plants which are fitted to be used in such positions, and by making a right choice of species, according to the object and importance of the site, a second waterside garden may be created with the happiest results. Like all other schemes of decoration, that of water places in our gardens demands good taste in conception if it is to appear to the eye a happy imitation of natural scenes.—JULIUS RUDOLPH, in *Revue Horticole*.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

DECEMBER 13.

THIS, the last meeting of the year, but not the last by one as it pertains to the society's arrangements, was not a large one, but it was, all the same, full of interest. Orchids on this occasion predominated in a marked degree, several excellent groups being staged, notably that from the Burford collection, which was very rich in *Calanthe* hybrids, and another in which *Cypripediums* and other good things were finely represented from Cambridge Lodge. Trade groups came from Chelsea and Enfield. Before the floral committee nothing was of greater interest than the charming winter-flowering *Begonias*, notably *Winter Cheer*, which is an invaluable plant and rightly named; also *Gloire de Lorraine*, of which the plants were even better than usual. A few late *Chrysanthemums*, very fresh, were staged, also a splendid assortment of winter-flowering *Geraniums* from Swanley, which even surpassed those usually sent from that source. The fruit committee had but little to do, which was to be regretted, inasmuch as fruits for the approaching Christmas season might have been made a special feature. The day being a dark and gloomy one, it was not possible to see the exhibits from the colour point of view to the best advantage. The Drill Hall sadly needs redecoration throughout and in rather lighter colours than those now prevailing.

Orchid Committee.

A first-class certificate was awarded to—

CYPRIPEDIUM ISSIGNE (Harefield Hall variety).—This is a very large form, the dorsal sepal over 2 inches across, the basal half green, thickly spotted with dark brown, the upper portion white with some large purple blotches at the base, the lower sepal green, thickly spotted with brown.

The lip is also large, yellowish green, suffused with brown. The finely-grown plant carried seven flowers. It came from Mr. E. Ashworth, Harefield Hall, Cheshire.

Awards of merit were adjudged to the following:—

LÆLIA DICBYANO-PURPURATA, a hybrid derived from the species indicated in the name. The petals are pale rose, splashed with purple on the edges, the sepals also pale rose. The lip, entirely without the usual fringe seen in this section of hybrids, is rich crimson purple, with the front pale rose. The side lobes are yellow, lined with purple at the base. From Messrs. J. Veitch and Sons.

CALANTHE REVERTANS.—This is, perhaps, the darkest *Calanthe* that has been seen. The flowers are as large as those of an ordinary *C. Veitchi*, the colour being an intense rose-purple. The plant carried a raceme of twenty-four flowers and buds. From Sir T. Lawrence, Burford Lodge, Dorking.

Messrs. J. Veitch and Sons sent a small but choice group. In the back row was a grand plant of *Cymbidium Tracyanum*. *Oncidium pectorale* (finely flowered), *Cypripedium Lceanum*, a grand plant of *C. insigne* Chantini with seven flowers, several finely-flowered plants of *C. Arthurianum* and its spotted variety *C. A. pulchellum*, *C. Niobe* and *C. Niobe superbum* were also well represented. Several forms of *C. Euryades*, *Dendrobium atro-violaceum*, and *Ionopsis paniculata* were also included. Among the *Cattleyas* were good forms of *Lælio-Cattleya Decia*, *L. C. Eunomia*, and *Lælia Novelty*. *L. C. Semiramis* has the intermediate characters of the two parents, while in *L. C. Frederick Boyle* the sepals and petals are deep rose; the lip rich velvety crimson-yellow, lined with maroon in the throat. *L. C. Andreana*; *Lælia Omen*, flowers rose, veined and suffused with a darker shade of colour; and *Cattleya Ariel*, which could scarcely be distinguished from *C. Bowringiana*, were also shown. A silver Banksian medal was awarded. Messrs. H. Low and Co. sent a nice group, prominent among which were a dark form of *Cymbidium Tracyanum*, finely-flowered and good varieties of *Oncidium tigrinum*, a grand plant with three flowers of *Lælio-Cattleya Aurora*, *L. C. Appolonia*, a good form of *Cattleya aurea*, a lovely dark form of *Lælia Goldicana*, *Calanthe Veitchi alba*, and a finely-flowered plant of *Sophranitis grandiflora*. The *Cypripediums* included most of the hybrids and species flowering at this season. A silver Banksian medal was awarded. Messrs. F. Sander and Co. sent a small group, consisting of finely-flowered *Oncidium*s, grand forms of *Cypripedium Lceanum*, and numerous hybrids of the *Cypripedium* family.

Sir T. Lawrence was awarded a silver Flora medal for a group of most interesting *Calanthes* and *Cypripediums*. The most remarkable among the *Calanthes* was a batch of exceptionally dark forms of *C. Veitchi*, which were in striking contrast to the rosy pink flowers of *C. Victoria Regina*, next to which was arranged a batch of the pure white *C. Veitchi lactea*, which showed up the rich colour of *C. burfordensis*. *C. Bella*, with its dark rose-tinted flowers and rich purple disc on the lip; *C. versicolor*, pure white, with a bright rose disc; and *C. amabilis*, a distinct form, rose, with a white disc, were also worthy of note. Among the *Cypripediums* were beautiful forms of *C. Lceanum*, the variety *C. L. giganteum* being exceptionally fine. *Odontoglossum Coradinei* with ten flowers and buds, and *O. triumphans-crispum*, which resembled a yellow-ground form of *O. Wilkeanum*, were also shown. Mr. R. J. Measures was also awarded a silver Flora medal for a large group consisting of numerous *Cypripediums* of the better forms of *C. insigne*, which included *C. i. Sandera* with two flowers, *C. i. Ernesti* with three flowers, *C. Wottoni* (*C. callosum* × *C. bellatulum*), a seedling (*C. callosum* × *C. leucochilum*) resembling *C. Wottoni*, the seed of which was sown in January, 1896; *C. Allanianum superbum*, and numerous forms of *C. Lceanum*. *Vanda Amciana* was also included.

The most prominent among the *Masdevallias* were *M. ignea*, *M. calax*, *M. pachyura*, and several plants of *M. tovarensis*. *Pleuroballis punctulata*, with its green and purple flowers, and *P. conanthera* were also represented. Among the *Oncidium*s were some finely-flowered plants of *Oncidium cheirephorum*. *Dendrobium endocharis*, *Cattleya labiata*, *C. Miss Williams*, *L. C. elegans Schilleriana*, *Cymbidium Winnianum*, and finely-flowered plants of *Sophranitis grandiflora* were also included. Captain Helford, Westons-birt, Tetbury, was awarded a silver Banksian medal for a collection of cut Orchids, consisting of fine flowers, grand in form and substance, of *Cypripedium Lceanum*, *C. Charlesworthi*, and good varieties of *C. Niobe*. Among the forms of *C. insigne* was the yellow *C. i. Dorothy*. *Lælia anceps* and *Cymbidium Tracyanum* were also well represented. Mr. G. Robertson sent *Cymbidium Winnianum*, and Mr. de B. Crawshaw showed a finely-spotted *Odontoglossum Ruckerianum*. Mr. H. A. Burbury sent *Lælia anceps Burburyana*, a large form with an exceptionally dark lip, and Mr. W. C. Walker, Winchmore Hill, exhibited *Lycaste cruenta* and a fine plant of *Dendrobium aureum*, for which a cultural commendation was awarded. Mr. G. W. Law-Schofield sent a dark form of *Cypripedium Norma*. Mr. H. Little showed a fine group of *Cypripediums* in variety, the most prominent being *C. Lachmee* (*C. Veitchi* × *C. ciliolare*), one of the best hybrids of this section, petals spotted with purple. *Vanda cerulea*, *Cattleya Percivaliana*, *Lælia anceps*, and *Dendrobium Phalanopsis* were also well represented. A bronze Banksian medal was awarded. Sir W. Marriott, Down House, Blandford, sent a seedling *Lælio-Cattleya*, the result of crossing *L. C. elegans* and *C. gigas*, which resembles *L. C. Henry Greenwood* to a great extent. He also sent a new *Cattleya*, a cross between *C. Mendelli* and *C. gigas*, which the committee desired to see again.

Floral Committee.

A first-class certificate was awarded to—

ASPARAGUS SPRENGERI COMPACTA.—A distinct and valuable addition. In this the habit is less trailing than in the others; the outer branches, which are longest, droop a foot or 15 inches, and gradually diminish in length till those of the centre are not more than 6 inches long. Each frond gracefully droops over the former one in the most pleasing manner, and this, coupled with the rising fronds in the centre, renders it a most attractive plant. In the shade of green the whole plant is much darker than the type. This variety is said to have occurred in a batch of seedlings. From Mr. H. B. May, Edmonton.

The winter-flowering zonal *Pelargoniums* that were staged by the Messrs. Cannell and Sons, Swanley, were in marked contrast to the usual gloomy surroundings of the Drill Hall. On such a day, with fog hanging heavily overhead, these brilliant winter flowers appeal to one by their brilliancy alone. The group contained some fifty bunches or thereabouts, and in almost as many varieties, few duplicates being apparent. The following are the most conspicuous: *Niagara* and *Snowdrop*, very pure white, both of good form; *Mrs. Ewing*, white and pink; *Mark Twain*, rose-salmon; *The Sirdar*, a novelty with fine blossoms of crimson-scarlet; and *Mrs. Simpson*, white, with a centre of salmon fairly well defined. *W. E. Corden* and *Soldier's Tunic* are in every way first-rate scarlet shades, that, considering the form of the flower in conjunction with the colour, will take some beating. Then in the salmon shades where this is mingled with white, *Ian Maclaren* and *Duchess of Marlborough* are very fine, the latter being of the largest size also. *The Khalifa* is a salmon-salmon, Mr. P. Roath is salmon and deep salmon, and *Crabbe* is a salmon-scarlet surpassing all else in brilliancy of tone and fine form. Of quite a different pattern is *Rudyard Kipling*, a sort of carmine-magenta shade that is more distinct than beautiful. The whole bank was interspersed with small Ferns, and formed a very brilliant display at this season.

At one end some vases were filled with *Chrysanthemum* Miss Harvey, a decorative kind of rather small size, having the petals twice or thrice forked. It is a pretty kind, and for small vases or the like would be useful. A silver-gilt Banksian medal was awarded. Mr. Wells, Redhill, brought a fine lot of his favourite flowers, probably the last display for the season. A few of these deserve a passing note for their good form so late in the year; *Sunset*, a pleasing amber-gold, quite fresh-looking; *Snowflake*, very pure; *Redhill Beauty*, soft yellow, perhaps a trifle too pale under artificial light; *Mrs. W. Butters*, a pretty decorative with forked petals; *Nellie Pickett*; *Mrs. C. Brown*, white, and good for the season; and *Mme. Philippe Rivoire*, white, and rather reflexed in character. A fairly good yellow bronze is *Lucy A. Thompson*, and a good incurved Japanese among yellows is *Georgina Pitcher*. Of a similar shade is *Mons. Veillard*, but of a more reflexed type. *Mme. H. de la Rocheteire* is a greenish white bloom, but the habit is rather weak and thin, otherwise the flower is the best of its class we have yet noted (silver Banksian medal). Mr. H. B. May, Edmonton, had another of his fine exhibits of the well-known winter-flowering *Begonia Gloire de Lorraine*, the plants filling the entire side of a table through the centre of the building. Many of the examples were in reality bush-trained specimens, into which considerable labour had been put. From a cultural point of view the plants were excellent. The largest plants were close on 20 inches through and about the same in height. Thinly disposed throughout, and with a variety of Ferns interspersed and forming a groundwork, the plants appeared at their full worth. Examples of *Adiantum Farleyense* drooped gracefully from raised pedestals, the several forms of *Asparagus Sprengeri* occupying similar though perhaps loftier positions. Of this plant, the type included, there were three forms, all very distinct, viz., the type, with its long trails freely branched as it were; *A. S. densissimus*, the trailing shoots of which depend to about half the length of those of the first and of a heavier, densely-set habit; and the most recent addition, already described (silver-gilt Banksian medal). Messrs. James Veitch and Sons, Ltd., Chelsea, had fine batches of their new winter *Begonias*, *B. Ensign*, *B. Myra* and *B. Winter Cheer*, the two first paling considerably beside *Winter Cheer*. This is indeed all its name implies, a really bright and cheerful flowering plant for the winter season. The flowers, too, are abundant as well as large, the slightly drooping character of the blossoms adding that touch of gracefulness that in many plants is wanting. A specimen of the hybrid *Rhododendron Exquisite* was also staged. This kind produces a handsome truss of rather deep canary-coloured flowers, the latter large and very showy (silver Flora medal). From St. Albans Messrs. Sander and Co. sent handsome specimens of *Acalypha hispida* (*Sanderiana*), some of which were 3 feet to 4 feet high, with a score of the richly-coloured inflorescences, all beautifully coloured from base to tip. It is a striking characteristic of this wonderful plant that these brilliant appendages put on their colour as they emerge from the axils of the leaves, even those of an inch long at once assuming the fine colour they so long retain. This is a curious as well as interesting fact. A dozen fine plants of this were staged on this occasion. Other things included *Acalypha Godseffiana*, *Dracæna Godseffiana*, the dark green leaves freely spotted with white, and *D. Sanderiana*, of which some very beautiful and effective plants were sent. A couple of new Palms also in this group were *Linospadix Petrickiana* and *Licuala Jeaneneyi*, the latter a dwarf and sturdy species, the spreading fronds composed of ten openly disposed and abruptly blunt divisions (silver Banksian medal). Mr. C. A. Pearson, Frensham Place, Farnham (gardener, Mr. Prewitt), had a small group of mixed plants, such things as *Ericas*, *Begonia Gloire de Lorraine*, *Dracæna Sanderiana*, a few Palms, some

small bits of *Cypripediums*, Ferns, &c. A white Japanese incurved *Chrysanthemum* named Christmas Favourite came from Mr. Godfrey, Exmouth, the variety being very pure and having the large, broad petal of Kentish White. The flowers are neither large nor very full to the centre. From the same source came Queen of Pinks, a spreading flower, with narrow florets of a magenta-lilac shade. A few plants of *Primula sinensis* vars. calling for no special comment came from Mr. H. Eckford, Wem, Salop, while to Mr. A. Kingsmill goes the credit of being the exhibitor of the most minute yet complete flower on this occasion, viz., a scape bearing a solitary blossom of the inconspicuous green *Daffodil*, *Narcissus viridiflorus*. The scape is about 6 inches long, the segments of the perianth, perhaps, three-quarters of an inch long, and the exceedingly small corona about a quarter of an inch across.

Fruit Committes.

Only some half-dozen exhibits were staged, and these of no great merit. From Mr. W. Shingler, The Gardens, Melton Constable, Norfolk, came a nice bunch of Grapes. This was described as a seedling, the result of crossing Lady Hastings with Gros Colman, but the committee did not see any difference between this and the Gros Colman. A seedling Apple named Paroquet came from Mr. Ross, Welford Park Gardens, Newbury. It was a very nice-looking fruit, highly coloured, but not in the best condition, being over-ripe. Seedling Apples also came from Mr. J. Butcher, The Nurseries, South Norwood. A very good dish of Hoary Morning came from Mr. A. Dean, Kingston. A nice basket of *Oxalis crenata*, an Artichoke-like vegetable with pink-coloured tubers, came from Mr. Herrin, The Gardens, Dropmore. This will be a superior vegetable to *Stachys tuberosa*, being larger and better shaped, and Mr. Herrin will do well to show it in a growing state. Miss Breton, Forest Oak, Sandhurst, sent four roots of Caroons, but very small.

NOTES OF THE WEEK.

Iris Histrio and *Iris alata* are already in bloom here under glass but without heat, also *Lithospermum rosmarinifolium* and *Oxalis lobata*.—H. SELFE-LEONARD, Guildford.

Hessia spiralis.—This is probably one of the smallest of flowering plants, and one equally small in growth. The dainty white and pink blossoms, some half dozen in a scape, are as minute as they are interesting.

Senecio Galpini, with striking heads of intense orange, would create a most effective blaze of colour were the plants more generally free-flowering. As it is, however, the solitary flower-heads render the plant quite conspicuous, and with its blue-grey leaves the attractiveness is enhanced.

Rhododendron Exquisite.—This is probably one of the finest of the recent hybrid forms belonging to the javanico group, the large handsome blossoms being bell-shaped and widely reflexed. The tints is also large. In colour the flowers vary from rather deep canary to almost chrome-orange, the exact shade being by no means common among winter-flowering plants.

Chrysanthemum Christmas Favorite.—A white kind bearing this name was among the exhibits at the Drill Hall on Tuesday last. Of the habit of the plant or its freedom to bloom we know nothing, but of the flower alone it may be noted it was very pure, the petal firm in texture and broad, incurving to the centre. It is of a type intermediate between the old Lady Lawrence and Kentish White.

Plumbago rosea.—As a pot plant in the warm greenhouse at this season this is always attractive. In these days, however, when the demand for valuable flowers for cutting is daily on the increase, plants of this type, the flowers of which possess little value when cut by reason of their so quickly falling off, can be afforded but little space. Otherwise the dainty sprays and the richly-coloured flowers should be in demand.

Narcissus viridiflorus.—In spite of its inconspicuous character, a good deal of interest centred

around the solitary example of this singular species brought on Tuesday last by Mr. Kingsmill to the Drill Hall. Only a single-flowered scape was exhibited, the predominant colour green, and, of course, not at all showy or attractive to the naked eye. Otherwise, however, there is much to admire in this curious flower.

Ixora incarnata.—This somewhat rare species was noted recently at Kew, where a small example was flowering. In its general character the species in question is very distinct from most kinds; indeed, when not in flower, a casual observer may take it for one of the Javan *Rhododendrons* were it not for the temperature in which the plant is found. The flowers individually possess the curious habit of completely reflexing the divisions of the corolla, thus giving the plant a rather singular appearance.

Name wanted.—In reply to "G. S. S." it is probable that the plant of which he has a sketch from Ningpo is *Pineilia tuberifera*, a pretty little Aroid found widely distributed in N. China and Japan. It is figured in vol. xix. of *Somokou Zousett's "Flora of Japan,"* and I enclose a tracing of *Somokou's* figure. The slender leaf and flower-stems spring from a tuberous root-stock, and the leaf-stalks produce small tubers in the way "G. S. S." describes. Various species of *Amorphophallus*, *Tacea* and other Aroids produce tubers on their leaf stalks.—F. W. BURBIDGE.

Two fine Violets.—Messrs. Isaac House and Son, Coombe Nurseries, Westbury-on-Trym, Bristol, send us some fine blooms of two Violets. In the variety Princess of Wales the flower-stalks are from 6 inches to 8 inches long and almost erect, the blooms as large as those of a miniature Tufted Pansy. In Italia the blooms are not quite so large, the leaves, too, being smaller. We understand that as grown by Messrs. House and Son, Italia is far more free-flowering than Princess of Wales. Both are well worth adding to a collection including also *La France*, with immense flowers of a rich blue colour.

Begonia venosa.—Grouped together in batches of half a dozen plants, this species produces a fine effect by reason of its distinct and well-marked leaves. In general character of growth and habit this Brazilian *Begonia* is widely removed from most other kinds, if not, indeed, from all. Several plants of it are now flowering at Kew, where a really extensive collection of species and hybrids affords a good array of blossom and a far-reaching interest throughout the year. The flowers are white and somewhat small for the size of the plant. The plant is attractive by its foliage, the surface of which is covered with a short dense tomentum.

Euphorbia myrsinites.—The numerous long prostrate growths of this plant, covering as they do a large space superficially, render it attractive now that flowering plants in the rock garden are scarce. At such times the value of this and similar subjects is apparent, the more so because the glaucous blue-grey tone of the leaves is not a thing of to-day—it is permanent even in the oldest stems. The plant is one of a few of its class in this respect, and, being readily accommodated in ordinary soil, deserves to be more freely cultivated. Seeds, where these can be obtained, should be sown early to make good plants, or the young shoots slipped off in spring root freely without much moisture.

Nerine undulata.—It is doubtful whether any species of this genus longer retains its beauty than this. It is so light and elegant in the general formation of the head of bloom as to make it worth attention as a cut flower, for which purpose the slender stems are well suited. A solitary example gives but little idea of its beauty compared with, say, a group of half a dozen or more pots with three bulbs in each. As the flower-stems rise to nearly or quite 18 inches high, the colour as much as the wavy character of the perianth segments is seen to advantage. A plant that remains in good condition for nearly or quite two months of the most sunless period of the year should merit attention.

Galanthus macedonicus.—Under this name I received several years ago from Italy a Snow-

drop which comes into bloom early in December. The name appears to have no authority in its favour, but for convenience I grow it under its catalogue title. It is evidently one of the varieties of *Galanthus nivalis*, and differs from the Albanian Snowdrop, to which I referred on p. 479 of THE GARDEN of December 10, in its greater vigour and in the considerably deeper green of the flower stems and spathe. Although more vigorous in growth, it does not increase so quickly as the Albanian variety, but this may perhaps be due to the drier position it occupies in my garden. The flowers are about the size of those of our ordinary Snowdrop.—S. ARNOTT.

Zauschneria californica. I would not have Mr. Arnott despair of flowering this in the north, though the general failure of the plant to bloom there is notorious. It must be a cold or short season in the south when it fails there, and I suspect that the single failure in Cornwall which he reports was casual and accidental. Here (in Surrey) the plant is a great stand-by for a late red among dwarf or rock plants. As such, indeed, I know not its equal. If he thinks it worth the trouble (as I should), I can scarcely doubt he would succeed by bringing on plants in pots under glass and planting or plunging them out in June, for, as he has doubtless found, the plant is quite easily grown, and the cause of the failure to bloom is simply the comparative coolness and shortness of the northern summer. There are at least two varieties of this plant, both worth growing.—H. SELFE-LEONARD.

— There is one way at least of growing this distinct plant effectively, and that is on a wall. If its roots are planted in good fibrous loam and pushed into holes on the face of a sunny wall it flowers splendidly in the late summer or autumn months. I laid a few masses of its roots on the top of a brick wall and covered them with road scrapings, and the result was also satisfactory, as planted in deep, rich, moist soils the plant grows freely enough, but rarely flowers well, and a friend of mine who had seen the plant wild in California once told me he had never seen it so bright and showy as one August day on the face of the river wall at Mount Usher, in Co. Wicklow.—F. W. BURBIDGE.

— My experience of the above plant is most satisfactory. Four years ago I planted two small plants out of 3-inch pots in a steep rock garden facing south at Malvern. After dividing the roots, two months later, I had seven large plants, all of which flowered profusely in the autumn. The soil was originally a stiff red clay, but I removed the surface and rebuilt the rockwork, adding new soil. The roots got down into the clay and ran to a great distance. I have since given away several roots, all of which have flowered well. I believe that the plant requires a dry, sunny situation. I saw plants at Mr. R. Smith's Worcester Nursery which stood the hard winter four years ago, and grew in the following summer into great bushes covered with blossom.—S. H. BOYLE.

Anomatheca cruenta.—In a light sandy soil and mild climate near the sea I find no difficulty in growing this charming little bulbous plant, but even in cold, heavy soils it may be grown by a little preparation of the soil near the walls or even on gravel walks in front of hothouses, &c. The plant seeds so freely and the seeds grow and flower so quickly, that it is well worth growing in pots for cool greenhouse or even window decoration. But in most gardens it would be found possible to cultivate it from bulbets or seeds planted or sown in shallow sandy soil in any sheltered nooks or corners near the warm plant houses or vinerias. It is one of the neatest, brightest and most distinct of all Cape bulbous plants, and should find a place in pots, on rockwork or borders more often than it does now.—F. W. B.

Callicarpa purpurea.—Few stove plants at this season of the year are more showy than this. It is well worth growing not only for its value in the greenhouse, but equally so for its use in

decorations generally. In many an odd corner where Palms and Poinsettias are now used for effect this striking subject should appear to advantage. For a long time the berries retain their rich colour, which should be borne in mind by those requiring showy plants of easy culture. Plants of two years' growth and upwards when pruned rather hard in spring should be kept some time in a close, warm house to develop growth and flower, from which time the usual summer heat in such places is in most cases sufficient. As the autumn approaches, the fruits, which occur plentifully in axillary clusters, put on their colour and remain attractive for some weeks.

Hybrid Cypripediums.—The contribution from Westonbirt of so remarkable a series of hybrid Slipper Orchids was freely commented on at the Royal Horticultural Society's meeting on Tuesday last. The manner of setting up the blooms was also the subject of comment. Indeed, it was unfortunate that what was obviously so valuable an assortment should not have been disposed to advantage. As it was, the reference tickets, as also the blooms in some instances, were so huddled together that an inspection was well-nigh impossible without a complete sorting of the whole. Much of this could have been avoided by expending another half hour in their arrangement and using smaller bottles. In this way visitors would have been afforded an opportunity of comparing the many beautiful things the collection contained.

Mr. Edward Whittall's new Snowdrop.—Almost coincident with the appearance in THE GARDEN of December 10 of Mr. Burbidge's note regarding Mr. Whittall's capture by brigands and subsequent release the first flowers of our good friend's new Snowdrop opened here. Out of a large number of bulbs, only two have as yet flowered. It is also unsafe to pronounce a definite judgment upon Snowdrops the first season after replanting, especially if they have been dried off. There is, however, sufficient evidence to form an opinion that this Snowdrop will justify Mr. Whittall's statement that it is the finest form of *Galanthus Elwesi* he has yet seen. The flowers which have opened and the many yet to come bear out this, and the broad, bold leaves and tall growth promise well for the future of this new Snowdrop. I have often regretted that Mr. Whittall's name has not as yet been more definitely attached to the Snowdrop, even if only to a variety of Elwes's species. An opportunity is now, I think, afforded us of doing so by calling this *Galanthus G. Elwesi* var. *Whittalli*.—S. ARNOTT.

Colchicums not flowering.—While the Meadow Saffrons are, as a rule, free bloomers, there are, I believe, some which are often unsatisfactory in this respect. Of these I think *C. Parkinsoni*, which is also found under other names, is among the worst. It does not flower any better in poor than in rich soil, and what one would consider a good medium gives little better results. One generally finds that in a rich deep soil the flowers of the Meadow Saffron are not only larger, but also much finer in colour, and I know several gardens with soil of this description in which there is no scarcity of blooms. Mr. Wood has given a good explanation of the reason why the Colchicums fail to bloom in some gardens. In such his remedy might be practised. Not only do the Meadow Saffrons look better in a dense mass, but the closer they are the less apt are they to be blown down—one great cause of the short-lived beauty of the flowers. In removing, too, one should be careful as to the precise time. This operation ought to be performed when the leaves turn yellow. If left until later it is almost impossible to remove the deep, closely-packed corms without serious injury.—S. ARNOTT.

Selaginella denticulata.—The hardness of this pretty Selaginella is a subject of interest to many who use plants of similar character as carpets for bulbous or taller herbaceous plants. One feels inclined to agree with Mr. John Wood in his interesting and practical communication in

THE GARDEN of December 10. Here I have found *S. denticulata* hardy for some years, but only in certain conditions, depending principally upon the character of the soil, and also upon the establishment of the plants. Those which have succeeded have been on very dry soil and in fairly sheltered positions. They have also come generally from pots or boxes of seedling bulbs raised in the greenhouse and planted out without disturbing the ball or square of soil any more than could be avoided. The most flourishing patch I have is one in a shady place. It originated from a few young plants which have appeared on the surface of a box of seedlings of *Galanthus Elwesi*. The box had become decayed when the Snowdrop bulbs were but small, and many were too minute to handle with safety, so that the box was taken to pieces, leaving the oblong of soil undisturbed. I think those who wish to try this Selaginella in the garden would do well to plant it out of a pot without disturbance of the roots.—S. ARNOTT, *Cars Thorn, by Dumfries, N.B.*

Iris stylosa.—This Iris, though it has for some two or three weeks been flowering in sheltered places, gives promise at the present time of a good season of its delicate blossoms. Nothing is more choice or beautiful in the hardy garden at the present moment than this where it lies snugly at the foot of a sunny wall. Here a certain dryness for its roots, the result of contact with the surrounding masonry, may have something to do with the perfect health and the certain freedom of flowering that appear inseparable from these plants. Giving little trouble and furnishing a supply of the delicate and pretty blooms at such a time would appear ample recommendation for planting similar positions freely with the same subject. Not only does the plant grow and flower, but there is evidence that in such positions the foliage escapes the cold and cutting winds that in the open frequently play such havoc with the plants. Such a check to foliage could scarcely be sought else than a check to its flowering. By planting in the position suggested much of this may be avoided, in the warmer counties at least. If more is needed to be told of this beautiful winter flower, it may be found in the variation from the original, the variety *speciosa* and the lovely white kind adding even greater beauty to the species above noted.

Scilla italica alba.—My note on this variety of the Italian Squill has not only been the means of giving me some information regarding its whereabouts, but, through the kindness of my correspondents, of giving me the opportunity of growing it again—an opportunity of which I shall be delighted to avail myself. It appears to have been one of the many treasures in the garden of the late Rev. John Nelson, of Aldborough, and it was from this source that the bulbs I have heard of have come. As I mentioned in my note in THE GARDEN of December 3, this Squill is figured in Maund's "Botanic Garden." In the plate the blue and the white varieties are both shown, and the writer of the accompanying letterpress says: "We owe the possession of both varieties, the blue and the white, to the Rev. W. Bree, of Allesley. The latter is, however, very rare in cultivation." About fifteen years ago, in giving it to a friend of his who has kindly communicated with me, Rev. Mr. Nelson said, "I believe this to be unique." From this source it was sent to Kew and one or two other public gardens. A lady gardener well known to all interested in hardy flowers, and who has most kindly written me, procured her bulbs of the white Italian Squill when Mr. Nelson's plants were dispersed, and it was from her stock that my only bulb came, but by way of a nursery in Holland. It may be of interest to some to know that the late Mr. Niven, of Hull, who edited the last edition of the "Botanic Garden," remarks with reference to the plate of *Scilla italica*: "The foliage, as here represented, is decidedly narrower than that of the plant we now cultivate." One is disposed to agree with Mr. Niven on this point. The flowers, although small, are faithfully represented.—S. ARNOTT, *Cars Thorn, by Dumfries, N.B.*

PUBLIC GARDENS.

Gift by Lord Ellesmere.—The Earl of Ellesmere has presented the Worsley District Council, which has jurisdiction over a portion of his Lancashire estate, with a large open space known as Roe Green, several acres in extent, to be used as a pleasure ground. Lord Ellesmere, in conjunction with the trustees of the Duke of Bridgewater, is spending between £300 and £400 in enclosing the ground.

Open spaces in London.—At the monthly meeting of the Metropolitan Public Gardens Association, held at 83, Lancaster Gate, W., the Earl of Meath, chairman, presiding, progress was reported with regard to the laying-out of the Paragon, New Kent Road, and Albion Square, Dalston. It was agreed to plant trees in Upper Street and Hamerford Street, Islington, and to offer trees for certain sites in the Strand and the City. It was agreed to offer seats for the churchyard of St. Andrew Undershaft, to memorialise the Metropolitan vestries and district boards respecting tree lopping in London, to urge the Hornsey District Council to preserve the Queen's Wood in its natural state, to continue negotiations with respect to the proposed opening of Finsbury Circus, Christ Church Churchyard, Blackfriars, and other spaces.

OBITUARY.

MR. W. PRAGNELL.

WE regret to announce the sudden death, on Tuesday, December 6, at the age of sixty-one, of Mr. W. Pragnell, who has been gardener at Sherborne Castle, Dorset, for forty-five years, having succeeded his father in that position. He had visited Sherborne in the early part of the day, and on reaching home suddenly fell forward and expired, striking his head against the table in the fall. Many of the readers of THE GARDEN will remember Mr. Pragnell as a prominent exhibitor and judge, and he at one time used to be a frequent contributor to the gardening papers. Visitors to the Royal Horticultural Society's meetings in the old days of South Kensington may remember the fine collections of fruit and vegetables he used to show. He leaves a widow, four sons, and two daughters. The funeral took place on Friday at Castleton, and was largely attended by the residents and friends in the district, where he was held in the greatest esteem.

The weather in West Herts.—During the first twelve days of the present month there did not occur a single unseasonably cold day or night. Since then the days have been again warm, but on the two nights the exposed thermometer showed 6° of frost—by no means unusually low readings for the time of year. At the time of writing the soil is about 4° warmer than the December average at 1 foot deep, and about 6° warmer at 2 feet deep than the mean for that depth. Since the beginning of the month 1½ inches of rain have fallen, which is about a seasonable quantity for the first half of December. There has again been a poor record of sunshine, the average duration for the last four days being less than half an hour a day.—E. M., *Berkhamsted*.

BOOK RECEIVED.

"Rules for Judging." Second edition, revised. Royal Horticultural Society, 117, Victoria Street, S.W.

Names of plants.—*Spring Hill*.—1, *Helleborus altifolius*; 2, *Oacidium crispum*; 3, too shrivelled; 4, impossible to name from leaf only.—*J. Batchelor*.—*Asparagus Sprengeri*.—*M. C.*—2, *Cotoneaster frigida*; 3, sent better specimen.

Names of fruit.—*W. Ingram*.—3, not recognised; 6, Margil.—*M. C.*—Dutch Medlar.

ORCHARD AND FRUIT GARDEN.

PEACHES ON NORTH WALLS.

I CANNOT recall another instance in which north walls have been recommended for the growth of Peaches, and thus I am somewhat surprised that in "G. W. S.'s" case (p. 462) it should have been sufficiently remunerative to recommend it to others. There is a certain amount of caution in the adoption of such cool sites given by "G. W. S." which I certainly think due to the case in point, but, not having proved the possibilities of Peach-growing on north walls, I am not prepared to say what some soils and gardens may be equal to. One thing I am quite sure of is, that Peaches would be a signal failure in such a position in these gardens. This I can ascertain from their condition on a more sunny west wall. I would, therefore, not venture to waste trees, valuable space, and time in attempting to grow them in cold soil and without the aid of sunshine to mature their growth. "G. W. S." observes that there is great gain in having Peaches for four or five months from open walls, and says this can be accomplished from more suitable aspects if the kind of tree is studied. It is easily possible to have ripe fruit from early, mid-season, and late kinds from June to the end of November from a south wall, if there is enough space at disposal for planting a sufficiency of trees and in variety. East and west walls afford suitable sites for Peaches in some gardens, this allowing of a more extensive planting, and where such is the case, what need is there for attempting to fill spaces on a north aspect, which can be utilised with much greater certainty for Cherries (dessert and Morello), Plums, Pears, or even late Gooseberries grown in cordon fashion? From a south wall, Sea Eagle and Princess of Wales are by no means to be despised when perfectly developed and allowed to ripen fully before being sent to table. I think both the latter varieties are often condemned from a flavour point of view, simply

because they are used too quickly. Gathered and placed for a few days in the fruit room in a wool-lined box, Sea Eagle becomes decidedly melting and rich in flavour; gathered direct from the tree and sent to table, quite the opposite happens. For this reason I do not see any justifiable ground for planting midseason sorts, such as Royal George and Stirling Castle, on a north aspect simply on the remote chance of bringing them into competition with the late ones. At Heywood, Mr. Robinson for several years past has grown some exceedingly fine Peaches on an open wall, Sea Eagle, Barrington, and Princess of Wales comprising the late varieties planted. There has not been the slightest suspicion of failure during the past six years, though the protection given is only an overhead glass coping. Each evening following a hot summer's day the trees are well syringed, insect life suppressed before any injury is done by them, and summer and winter pruning and nailing carefully carried out. This, with an occasional dressing of artificial manures to the surface of the border, is the treatment given and from which such excellent results are obtained. For early and midseason use there are Condor, Grosse Mignonne, Dymond, and Violette Hâtive, varieties that give a long season of Peaches that are not surpassed in any respect by those grown indoors. If to these are added the earlier Waterloo or Early Alexander, a period of four or five months would be covered in which ripe fruits would be easily obtained from a south wall. It is true that these positions are frequently occupied by fruit houses, and then the grower of outdoor fruit must necessarily select east or west aspects, which, though in some, are not always so satisfactory as the south wall in every case. It is, I think, very clearly proved that a north wall is unnecessary for maintaining a long succession of outdoor Peaches.

W. S.

Peach Royal Charlotte.—This Peach seems to have become almost extinct. I know of only

one tree, and that is in a Peach house in a garden in Lincolnshire. The gardener, who has had a long experience in Peach growing, considers Royal Charlotte the best all round variety he has ever grown. Several years ago the tree lost some of its branches and seemed as if it was dying, but it was cut hard back to within a little distance of the stock, which induced it to break into a fresh growth, and it is now as profitable as ever again. In size and general appearance the fruit favours Royal George, while the flavour is delicious.

—J. C.

Grape West's St. Peter's.—This is a really useful Grape of excellent flavour, and, where good quality is esteemed, well worth growing. It is by no means a large-bunched or berried sort, but in this respect just the thing for table. It likes a little heat, and I have grown it well in a mixed vinery with Alicanto, Lady Downe's, and Trebbiano, where it hung in good condition till the new year. Its keeping is one of its chief recommendations, as it comes in useful when the Black Hamburg is gone. West's St. Peter's was a favourite Grape with the late Mr. William Thomson. It is strange it is not more generally grown.—C. N.

Syringing Vine foliage.—In ordinary cases red spider, if taken in time, may be eradicated by sulphur fumes. In high-lying gardens, however, and where the soil is light and the sub-soil gravel, I have known the pest to be almost invincible, especially if the vinery had large panes of glass in the roof and little woodwork. You might sulphur one week and spider appear again the next. In such an extremity there seems to be no alternative but syringing the foliage with soft water. If the laterals are arranged 18 inches apart a careful man can do the work without much bunch disfigurement.—C.

Apple Bramley's Seedling.—At p. 430 Mr. Prinsep has a note on this Apple. His experience with it exactly corresponds with mine. It is one of the largest Apples I know. In an orchard recently under my charge it was the largest and healthiest tree of any, but in fourteen years it only bore one crop, and that a poor one. A near neighbour of mine had a similar sized tree just as unproductive. My tree was growing in light soil. Mr. Prinsep's soil is heavy, so that

it seems it is shy in any kind. No fault can be found with the individual fruits, which are large, and retain their weight until late in the season. It is a capital baking Apple, but needs a good deal of sugar to render it palatable.—B. S. N.

Pear Jargonelle.—There are varying estimates placed on the merits of this summer Pear, some setting a high, others a low value on it. Personally, I think it has been much over-rated, and only in exceptional cases have I found it deserving of much favourable comment. It is a Pear I should not plant except under special request; its shy-bearing on a wall and ugly gait in growing as a pyramid or bush certainly are not strong recommendations in its favour. One of the few places where it succeeds is at Marston, Frome; in the heavy soil there, and with unlimited head-room it seems to have found an ideal home. Restricted in branch, it is very light cropping with me—in fact, not worth the space occupied.—S.

Plum Pershore.—Mr. Crook asks whether I have seen the above Plum doing well out of the midlands. I have not, but I learn on good authority that in some districts in Kent it grows freely and crops heavily. I presume Mr. Crook has the true variety, as it is strange that a Plum which carries such heavy crops in the market gardens of Worcestershire should refuse to do with Mr. Crook in his favoured climate, although doubtless soil and situation have a great influence on certain sorts of Plums. Mr. Crook mentions Goliath. I was under the impression that this Plum was extinct. I remember my father having a fine tree on an east wall at Thorndon Hall, Essex, many years ago. The fruits were very fine and valued for cooking.—J. CRAWFORD.

Apple Royal Jubilee.—This was one of the most noticeable Apples at the recent show at the Crystal Palace, the fruits being very fine, with a clear lemon skin. It is one of the best cooking fruits we have, its season being from November to March. It is not much known. If I mistake not, it was raised in Kent a few years ago, and is certainly worth room in all gardens where good keeping Apples are in request. It is also very late-flowering, so that the blooms often escape the late frosts. I am much pleased with the way young trees crop. It makes a strong growth, but not too gross, and is an excellent variety for heavy soils or exposed positions. It also crops very quickly when worked on old stems.—G. W.

Peach Early Silver.—In the southern parts of the country this Peach used to be a great favourite, and recently I saw some trees covering much wall space and that had produced some splendid crops of fruit. This Peach needs a warm soil. Few Peaches grown on the open wall are superior in flavour, the fruits being large where good cultivation is given. I find it one of the most reliable setters on a south-west wall, and in a favourable season the fruits are ripe in the middle of August. This is one of the most beautiful Peaches grown, having a skin of a delicate cream colour with a deep crimson on the sunny side, the flesh quite white throughout, and very melting and juicy. It was raised by Mr. Rivers forty years ago from a Nectarine.—S. H. B.

Early pruning of fruit trees.—"Dorset" does well to call attention to the necessity of pushing forward the winter pruning and nailing of fruit trees, as the less there is remaining to be done after Christmas the better. A mild autumn such as that just past is sometimes the precursor of a cold winter. Of this we had an experience in 1894 that will not soon be forgotten. What the future weather may be no one can predict, and pruning and nailing require to be done, as far as possible, before the coldest part of winter arrives. Like "Dorset," I have no sympathy with those who delay such work on the score of retarding buds, because this does not assure any great safety from spring frosts, which are so precarious that they may happen at any date, and there are occasions when the early bloom escapes, while the later flowers are overtaken and destroyed. There is so much uncertainty about frost, that the hastening or retarding of outdoor

buds is scarcely worth the trouble some put themselves to in trying to evade it. No outdoor tree can be gauged to flower at a time when it could be said to be safe from frost.—W. S.

SHY-BEARING APPLES.

I AM quite at one with "Norwich" in the advice given as to planting shy-bearing varieties of Apples, especially when it applies to amateurs' or other small gardens. Nothing is more disappointing than to plant good trees and then have to wait several years before getting any return. I have two young trees of Emperor Alexander, in size quite capable of producing several pecks of fruit, but during the past six years I think I may say they have not borne a dozen Apples. Here then is a variety which it is not advisable for amateurs to plant unless they are prepared to wait a long time before getting a crop. Old trees of Warner's King fruit freely here, younger ones are only moderately free-bearing, and in soil suited to it I believe it would prove a good market sort. Its fruits are of the largest size, will keep a fairly long time and are splendid for cooking. Most of my trees are on the free stock, which with strong soil tends to an excess of leaf-growth in young trees, root-pruning being an oft-repeated necessity. Peasgood's Nonsuch, whether in young or older trees, is not free bearing here, but generally it sets sufficient for the development of the size of fruit desired, and which gives the variety such a popularity for exhibition. King of Tomkins County on the free stock is very shy with me, but on the Paradise in poor soil it bears much more freely. It is, according to my experience, not of high quality for dessert and not large enough for cooking. It has a nice appearance and will keep a long time, but there is plenty of Apples more deserving of the planter's notice. I have only one tree of Bramley's, and this was grafted on an older tree four years since. It has not been a success so far, although its growth is very fine. It is neither a free bearer nor a good keeping Apple with me.—W. S.

—At p. 459 "Norwich" does well to call attention to the above. This is a point often overlooked in private gardens. In many cases the private grower is not altogether to blame, as the large fruit shows in a measure are answerable. At shows we learn nothing of the cropping qualities of these kinds. Of course one cannot always rely on catalogues, as in these most of the kinds have a good character. One kind "Norwich" failed with is with me a remarkable cropper in standard form. This is Warner's King. The other kinds he names fail with me, and I could add a good many more to the list.—S. M.

—I agree with all that "Norwich" says about these, and would add that not only should amateurs and those with limited space avoid them, but also if those who grow for profit do not do so, they will soon find the profit on the wrong side of the ledger. I have lately beaded down and regrafted a good many of the most highly extolled of all varieties because I was tired of looking for fruit year after year and finding none. I came to the conclusion that no amount of good qualities in other respects would ever make them profitable if they needed all sorts of coaxing to get any fruit at all on them, and as a rule these shy bearers are strong growers and make good foundations for kinds that do bear plenty of fruit. Of one thing I am quite certain, viz., that it is only courting defeat to plant such sorts as Peasgood's Nonsuch, Blenheim Orange, &c., as espaliers or in restricted forms of training of any kind, as they must of necessity be pretty closely pruned, this of itself militating against early fruitfulness. If you must have them in your collection, let it be in some form where the knife is very little used. With me Warner's King is by no means slow in coming into bearing, and its size makes even a thin crop profitable. My soil, being both light and warm, induces early fertility, but I have to be continually weeding out sorts that do not come up to the profitable standard of fertility.

Perhaps some kinds that do so well in the north do not take kindly to the south, and *vice versa*.—JAMES GROOM, Gosport.

Apple Maltster.—In referring to this Apple (p. 395), I stated that "tenderness in frost was attributed to it." That was said of it by several nurserymen, one especially from the midlands asserting such was the case. I also stated that it was not tender at Madresfield Court, hence it will be seen that my critics on page 458 have rather misread my note. Possibly the experience of the nurseryman with small trees differs from that of the gardener with old trees, but Mr. Crump has plenty of experience with the variety in both conditions at Madresfield. It is surprising how diverse in relation to flavour in Apples tastes are.—A. D.

Pear Van Mons Leon Leclerc.—Although not a highly flavoured Pear, this is quite equal to some varieties generally grown, as, for instance, Marie Louise d'Uccle. Well grown fruits are very handsome, being long and tapering, and they keep a fair time when ripe. The tree is not one of the best of growers, making rather long-jointed wood and having smaller foliage than most varieties. It is not an early or heavy cropper as a rule. I have seen fruit of enormous size gathered from trees in good Pear soil, and it makes a fine exhibition kind. A west wall suits it well. I have never tried it as a pyramid, so cannot speak of its suitability or otherwise for this form of growth.—B. S. N.

Bamboo canes on walls.—I think it should not be overlooked that because Bamboo stems are hollow, if fixed to walls for tying trees to and getting bruised, split or broken, so that insects could penetrate into them, they would constitute fine places of refuge for these pests quite out of the reach of insecticides. Of course it will be said that they need not be split or broken, but then they may be so, and doubtless would be. They might even in the winter become charged with moisture and be frozen, thus causing bursting. If the Bamboos be, as suggested, fashioned in the form of trellises and secured to walls, they must have a space of a quarter or one-third of an inch between them and the wall to enable tying to be done.—A. D.

Protecting open-air Figs.—Those who were fortunate enough to secure a fair crop of Figs this summer on trees in the open air will have found a difficulty in preserving them from the attacks of wasps and flies, at least by ordinary means. Old gardeners protected the fruit with muslin bags, and I do not think the plan can be beaten. They should be made sufficiently large to allow of a free escape of moisture, otherwise in wet weather the fruit is apt to decay. The best time to envelop the fruits is just when they commence to soften, that being when wasps attack them. Any fruits shaded by foliage should when bagged have the leaves moved away from them, so as to allow of a free circulation of air around and through the bags. The fruits should be picked in an under rather than fully ripe state, as in the latter condition a slight shower of rain is apt to start decay.—J. C.

Plums on south walls.—Mr. Crook (p. 429), referring to the early date on which he gathered his first early Prolific Plums, says, had it been on a south wall it would no doubt have been several days earlier. I have not tried this variety on such a wall, but Kirke's and Jefferson's I have, and found that they were not a day earlier on a south wall than others growing on east and west aspect. I take it that if these are not favourably influenced as regards early ripening, other sorts, including the one Mr. Crook mentions, would not be. I have come to the conclusion that south walls are not very well suited to Plums, and, generally speaking, are more profitably devoted to Apricots, Peaches, Figs and Nectarines. In very many cases, however, these fruits have suffered much loss of character during the past few years with not a few gardeners, because of the apparent un-

certainty of their crops, and their tendency to blister in the spring months. I must confess to having similar thoughts respecting them until quite recently, when the protective influence of glass coping has been brought to bear on their cultivation. Previous to the erection of coping, Peaches were hopelessly crippled with blister each year. The aspect now is so changed that Plums which were given space on a south wall now give place to Peaches.—W. S., *Wills*.

BUSH FIG TREES IN THE OPEN.

A SOUTH or west wall is the position usually given to outdoor Figs, and there can be no doubt that such is productive of the best all-round results. Trees planted in the angle where the two walls meet and trained on both give a longer succession of fruit. If the border is raised a foot or so above the level, so much the better, as then the roots get a maximum amount of warmth, while the foundation of the tree is being laid. Figs will, however, grow and fruit fairly well in bush form in the warmer counties provided the situation is sheltered and the root-run suitable. The finest examples of Brown Turkey I have ever seen indoors or out were in a garden on the east coast within a mile of the sea. The trees had originally been planted against the wall, but the lower branches had been allowed to ramble across the wide border into which they had rooted, forming, as it were, separate trees. On these close to the gravel walk hung in plenty, large, richly coloured fruit. These rambling branches derived very little actual warmth from the wall, although it certainly sheltered them. I remember two trees being planted in the south of England in front of and sheltered by garden offices, and they grew well and yielded good fruit. A wise course was adopted in planting. The trees were allowed to remain in the large pots, these being plunged in the beds prepared for them, all new roots being made from the surface, which had the effect of keeping growth in check for the first few years. The chief difficulty with trees so grown is protecting them during winter when they become large. The compost is an important consideration. Many are not aware in how poor a soil outdoor Figs, which are not bricked in like indoor ones, will grow. Mr. D. T. Fish explained in THE GARDEN a few years ago how he brought unfruitful trees into a fruitful state when living in East Anglia by removing the old soil and replacing it with one poor in character, in which broken bricks and mortar rubble largely predominated. The great thing with these bush trees is to allow no more growth than can be well exposed to sun and air. Trees that have been properly attended to this season ought to be well ripened, and, provided next spring is a favourable one, the year 1899 should be a record one for fruit. J. CRAWFORD.

Layering Strawberry runners into pots.

—With a view to save further labour and much trouble in watering, market growers usually layer their runners direct into fruiting pots. One of the largest lots I have seen so treated may still be seen at the Cobham Vineyard, where for the first time, having now greater house area, Mr. Bennett has 12,000 of Royal Sovereign in 6-inch pots. It showed great faith in the method and in the variety that all should have been layered into large pots at once, and that Royal Sovereign only should be relied upon. In preparing the pots not only was good drainage furnished, thus preventing all possible danger of the soil becoming saturated or clogged, but it was also made very firm and not too rich, good turfy loam being the chief constituent. The firmness of the soil and absence of fresh manure naturally caused the roots to develop slowly, so that leaf growth was equivalent and not coarse. The whole of the runners were taken from plants put out so late as the preceding September, and then not strong ones, having been bought in for the purpose. These were in pairs, grown 2 feet apart, and then a space of 3 feet divided each

pair. Of course the plants were not allowed to bloom; hence there was no trouble arising as to contact with fruit, whilst watering was of less concern than would have been the case with small pots.—A. D.

Pear Chaumontel.—Thanks to the past hot, dry summer, the flavour of Chaumontel Pear will be of a high order this season, judging it by a fruit which has ripened somewhat in advance of the bulk. This Pear, as a rule, does very well with me both on a south-west wall and as a low-spreading bush in the open garden. The latter crops the more heavily, whilst the former yields the larger fruits, and I should also add that both are on the Quince stock. It is seldom the trees miss cropping, but in the last three seasons they have borne remarkably well, and although the fruits would not compare with Channel Island produce as regards size, the flavour is equal to that of very many of our best Pears. It is also a very highly coloured Pear, the sunny side of the fruit being bronzy red, having a rather rough skin and a fairly regular outline. It has a pleasant rose-water flavour, the flesh being melting, juicy and rich when thoroughly ripened. It is also a good keeper. Its season varies considerably; in some years it is not ready until the end of the year or middle of January, in others from the end of November to the middle of December, everything depending on the character of the summer months, whether hot or the reverse. It is not a Pear that I should recommend being planted promiscuously, as it is only on warm soils and in favourable situations that it is a success, but, given these conditions, it is certainly worth growing, and I know of no other sort that pays better for high cultivation.—A. W.

Good cordon Pears.—All Pears are not alike suitable for growing in cordon form, some requiring a more extended growth to ensure fertility. For those with only limited means the following half-dozen will be found to give satisfaction in most soils and situations grown either as wall cordons or horizontally by the side of garden walks. Taking them in their order of ripening, both Williams' Bon Chrétien and Souvenir du Congrès are reliable as early autumn varieties. Where space is limited one only need be grown, as both ripen at about the same time and will not keep long. I give the preference to Souvenir du Congrès, although some think it rather short-lived on the Quince. Louise Bonne of Jersey not only crops well as a cordon, but colours its fruit beautifully when exposed to sun and air. Where the soil is strong and not well drained, special preparations must be made for this variety by removing the old soil to a depth of 18 inches or 2 feet, placing 6 inches of broken bricks in the bottom and filling in with a lighter, more open compost. The new Directeur Hardy, an October and November Pear, can be recommended as a good cordon variety, bearing heavily and being of extra good flavour. Beurré Superfin, a handsome russety fruit, forms a prolific cordon on the Quince, and should be in every collection; the flavour is rich and melting. Doyenné du Comice must be included in the most select collection of cordons, having, besides the richest flavour, size, appearance, and constant cropping qualities to recommend it. Olivier des Serres, invaluable for use in February and March, is very prolific as a cordon, the fruit being of medium size, round in shape, and of exquisite flavour. The tree is, moreover, of hardy constitution. The old Easter Beurré, in use at the same date, is a capital cordon variety, and although the quality is condemned by some, it is very sweet and refreshing, and keeps sound for a long period.—C. N.

NOTES AND QUESTIONS.—FRUIT.

Pear Beurre Bosc.—This is one of the best market Pears, for it is a strong grower and makes a fine bush, pyramid, or standard tree and is very prolific. Even in this exceptionally poor season for Pears, this variety has come out about the best of any. In fairly good seasons it is so prolific, that 5 or 6 bush-

would repay the grower well, but this season it was worth from 8s. to 10s. a bushel. Nearly all the fruit on a tree will be of about the same size, without a speck or blemish of any kind. I grow it as a bush tree.—J. G., *Gosport*.

Apple French Crab.—This fine old variety is not nearly so much grown as it deserves, for it is a very hardy, free-bearing kind, and keeps sound until Apples are in season again. It should not be gathered until the end of October or early in November, and I have seen it left hanging until December. If kept until the following spring it takes on a clear lemon colour and emits a very powerful perfume. Few Apples have such a fine flavour when mixed with Rhubarb in tarts. I find it one of the best for cultivating on its own roots.—J. G., *Gosport*.

KITCHEN GARDEN.

THE AUTUMN AND WINTER BROCCOLI.

THERE is no lack of really good autumn Cauliflowers, the Autumn Giant and others of the same type giving an ample supply well into October. The plants for the late autumn supply were none too plentiful on account of the summer heat and drought. The early Broccoli is this year not so good as usual, doubtless owing to later planting, the plants failing to make the desired progress afterwards. In my case the plants are smaller than usual. In the north, with more moisture, the plants suffered less, but in the south it was a difficult matter to keep them moving. Such seasons give cultivators a lesson. I shall plant earlier and make at least three different sowings and plantings. The plants put out in May and June have all done well, especially those which were planted in soil not dug over. Those that followed Potatoes are the smallest, and I fear they will not turn in at the season required. With too early planting and a favourable growing season the plants will turn in before the proper season. There is no great difficulty in retarding them. Soils will greatly influence growth. A rich garden soil is not the best for the autumn and winter Broccoli, as if the garden is at all sheltered they at the start make a rapid growth, grow up tall, with the result that the heads are weakly and there is far too much stem growth. The best plants are those in open fields. These invariably come in at the right season and the heads are of the best quality. As regards pests, few seasons have tried the grower like that of 1898. From early August to the end of September in a close garden it was necessary to go over the plants every week and pick off the caterpillars. Other growers may have been more fortunate. Only half a mile away the plants grown by the acre in fields with a poorer soil, but given more space, were scarcely touched by the pest. I note this to show the difficulties of growers in close gardens.

As regards varieties, they are many. I wish one could rely upon the good characters given some of the varieties as regards season and hardiness. Last year I had some new early varieties of Broccoli sent me for trial from Italy which turned out to be the Green Cape type grown forty years ago. I am not averse to new kinds by any means. We have had some splendid new things since the date I name; for instance, the Autumn Giant Cauliflower and the Protecting Broccoli, both most valuable additions, the latter the best I have grown for early autumn supplies. For many years Snow's Winter White was a reliable kind, but of late years my December supply has not turned in till spring. Those who, like myself, have a demand every day in the year for the Broccoli or Cauliflower will agree with my re-

marks as to our midwinter kinds, my chief complaint being that the varieties fail to turn in at the time stated. My best supply is obtained by growing large quantities of such kinds as the Self-Protecting and Superb Early White. The latter is none too early if not sown with the Cauliflower early in the spring; whereas the Protecting sown in April and May will give supplies in November or later. For later use I lift large quantities of plants when the heads are the size of a small ball. These are placed close together in frames, and treated thus they continue to grow. Frames are not a necessity, as the larger plants I place in an open shed, and thus get the first early winter supply. Superb White, though small when lifted early in December, turns in early in the year. I find the greatest scarcity is from December till February. This season tided over, there is less trouble. Of course, in the warmest parts of the country storing may not be needed, but in cold districts it is well to do so. S. M.

Potato Puritan.—I note at p. 489 "Narwich" writes very favourably of the Beauty of Hebron. I prefer Early Puritan, as this with me does not get disease so badly, but I doubt if the crop is quite so heavy. I am quite sure that few, if any, varieties are so profitable as these if grown in a light soil, and these qualities cannot be overlooked. Beauty of Hebron is more largely grown in country districts than any other Potato I know. On the other hand, these kinds are not good in wet soils, and in wet seasons there are great losses. Growers who do not care for many varieties will do well to note the faults of the kinds named and plant such as Windsor Castle, in my opinion one of the very best for crop, quality and long keeping.—G. W. S.

Cauliflowers in spring.—The good advice by "C. N." (p. 489) is very applicable at the present time. Those who are short of plants should sow a few seeds of such kinds as First Crop, Early Forcing, or a good selection of the Snowball. Last winter was one of the mildest we had for years, and I noticed a large percentage of the Cauliflower plants sown in August buttoned. I kept the smaller seedlings in the open, and they gave the first heads, but later than usual. I have referred to the need of sowing at this date or early in the year. I prefer sowing now, as plants raised in heat need more care and at times mildew badly. If sown thinly in boxes in cold frames and pricked off when large enough, they will give nice heads only a little later than those of autumn-sown plants.—G. W.

Potatoes failing.—"Amateur's" complaint as to his Reading Giant Potato tubers planted as seed failing to produce robust plants, and not decaying as all seed tubers ordinarily should, was found very common last season, arising from the excessive dryness of the soil. Generally, seed tubers, even if uncut, will decay, because there is in the soil sufficient moisture to promote that process. But sets that have been cut invariably decay because the wet surface seems able to attract moisture from the soil which cannot be conducted to the flesh when a stout skin armour interposes. There is some sense when planting in a dry time in cutting a small portion from off the lower end of each tuber so as to expose a portion of the flesh to the soil, as then decay commonly ensues. But it is not generally understood that the tuber flesh in its decay becomes food to the young plant's roots. Up to a certain stage the albumen in the flesh has sustained most development. Then in the decay of the cellular tissue food is furnished to the roots, and thus the seed tuber when decaying seems to be doubly utilised. I remember during a dry summer at Woodstock, when Mr. Robert Fenn was living at the rectory, he lifted some roots of new varieties of Potatoes on the skins of the seed tubers of which he had written with a pen and ink, and when lifted the seed tubers were found still hard and the writing

quite distinct. However, these things are pure accidents of a dry season. Probably no such similar drought will be experienced during the growing period of Potatoes for many years to come. Variety has nothing to do with the occurrence.—A. D.

The failure complained of by "Amateur" (p. 424) was undoubtedly caused by the prolonged drought. The very same thing occurred in this locality, and on a sufficiently large enough scale to prove a serious matter to the owner, who grows for market. When the crop was dug, the majority of the sets came out quite sound, the manure was not decayed, and even pieces of paper which had been ploughed in with the manure came out so sound that the printed matter could be mostly read. The soil was not wet when the sets were planted, and we never got enough rain to thoroughly moisten it during the growing time. In an ordinary year about ten tons to the acre would have been taken off the field; whereas the crop averaged no more than two tons to the acre, the majority of the tubers being under-sized. Some varieties have been much more affected by the drought than others, and probably another season the variety which has failed with "Amateur" would be satisfactory.—J. C., *Byfleet*.

EARTHING UP CELERY.

THOUGH there may not be so very much difference in the flavour of the various sorts of Celery when well grown, there can be no doubt that some are more hardy and stand a wet winter better than others. In this respect I have always given the palm to Leicester Red. After all, however, a good deal depends on when and how the plants are earthed up, although this season, owing to the soil being in a semi-dry condition in most gardens, late earthing up may not have the ill-effects it usually does. If at all avoidable, I do not like to earth up Celery when the soil is in a very wet condition, as the ridges do not drain so well and decay is encouraged. Moreover, worms, slugs, and other pests are then more at home than in drier quarters. With the earliest and second early rows, at any rate, it is generally practicable to choose fine weather for earthing-up. After the small bottom leaves and any suckers are removed, I like to loosen a little soil from the sides in the early part of the day and allow it to lie in the trench till the afternoon, breaking it up, if at all lumpy, with a five-tined fork; by this time sun and air have dried it, and it is in good condition for encompassing the plants. Tying up each plant lightly with strips of matting to prevent the ingress of soil is a good plan, but I prefer two men across the row, one walking backward and grasping the stick with both hands, while the other following brings the soil up to the plant with both hands. A height of 6 inches or so is enough for a start, and after this is done, a little more soil is forked down and all left level and neat. This moulding with the hands is continued till the tops of the hearts are reached. I find this secures good clean sticks. Where ground is plentiful, plenty of room should be allowed between the rows, so that the ridges may be of sufficient width till near the top. Unless this is done, the soil is very apt to collapse during heavy rains. Bring the ridge to a sharp angle to prevent wet finding its way into the hearts. C. N.

Autumn-sown Onions.—At p. 424 "A. D." notes that complaints are rife about getting the seed of autumn-sown Onions to germinate freely. Greater success would be achieved were growers to well water the ground twice at intervals of several days, or, better still perhaps, draw the drills, fill these with water, and after a few days sow the seed, mulching over the rows with old Mushroom manure to preserve the moisture. "A. D." is correct in stating that some varieties of Spanish and Globe Onions if sown in autumn stand the winter equally as well as the Tripoli. I have proved it in the case of Trebons, which is

one of the best for the purpose, and, as "A. D." says, the bulbs are always harder and keep better than those of the Tripoli.—N.

Pea Essex Rival.—Few Peas have remained in commerce so long as Essex Rival. I can remember it for at least thirty years, and although not generally grown in private gardens, it is, I believe, still regarded as a profitable variety by market growers in Essex. It is of hardy constitution, of medium height, and a profuse bearer, and what most people would call a good eating Pea. My opinion is that if those who grow Peas for market would sow Essex Rival, they would find it still one of the most reliable and profitable sorts.—C. N.

Pea Autocrat.—One can scarcely imagine a more popular Pea than Autocrat for main and late crops. It is only necessary to review the many reports of Peas which have appeared in THE GARDEN during the past few weeks to become convinced of the great merits of the variety under notice. It has an excellent constitution, bears freely, and does not attain to the ungainly height of some of the older sorts, which, though they possess great freedom of pod, large seed, and fine quality, are unsuited to smaller gardens by reason of the height to which they grow. Autocrat is a good dry-weather Pea and not so subject to mildew as many others.—W. S., *Wills*.

Lettuce Continuity.—The keeping up of a good supply of Lettuce throughout the past dry summer has been a matter of anxiety to many gardeners. Many varieties, particularly of the Cos section, either refused to grow or else ran to seed before hearts could be formed. Continuity has become popular, and in a dry season when water was scarce I have found it invaluable. By sowing and planting in succession I have experienced no difficulty in keeping up a good supply. The outer leaves of Continuity are brown, but the heart, which is large, is white and crisp. This variety showed no tendency to run to seed when other sorts grown were useless.—H. H.

Cucumber Tender and True.—Where very heavy crops of Cucumbers are not an object, I very much question if there is yet a better variety to grow than Tender and True. The flesh is tender, juicy, and well flavoured; in fact, it is the Cucumber for quality. It does not like rough-and-ready treatment, needing good culture, which it well repays. At one place where it was grown exclusively for private use pot culture was adopted. The pots were large and were half plunged in a bed of tan, the plants being liberally fed with liquid manure. A regular supply was kept up from spring till autumn. In appearance, few Cucumbers can surpass it. Many even of the finest looking Cucumbers are hard and dry.—NORWICH.

Winter Spinach failing.—The sowing and forwarding of the Spinach crop presented this season many difficulties, and after all one's efforts poor results are apparent, and now no compensation comes from all the trouble taken. I do not remember a season when the winter Spinach crop proved such a signal failure, and the cause is not clearly understood. Watering of the drills at the time of sowing and after the plants were well above ground was carried out at the expense of some other work, the crop being one of more than ordinary importance, because in daily demand. Two or three sowings were made as ground could be cleared of some other crop in August and September. The first sowing made a poor growth and went to seed even before it was ready for use. Later batches dwindled away after the rain had moistened the soil, a time when it was hoped a renewed growth would be established and sustained. All turned yellow in the leaf before the end of November, a condition I have not seen in a Spinach crop before—at any rate, not at such an early period of the winter. The autumn rains and mild weather have had no beneficial influence, so the cause for the collapse must be traced to the earlier seed-bed stage of growth.—S.

TREES AND SHRUBS.

THE HARDY SUMACHS.

(RHUS.)

THE genus *Rhus* occurs in almost every part of the temperate regions of the globe, and occa-

The Stag's-horn Sumach (*Rhus typhina*) grown to a single stem in the Royal Gardens, Kew. From a photograph by G. Champion.

sionally in the tropics. In all, there are more than 100 species described, but the majority of these are not known in gardens, and it is only about ten or twelve deciduous species that can be grown satisfactorily out of doors in most parts of this country. It is this small group that I propose to review in the following notes. A few of the Sumachs are notable for the beauty of their flowers—or rather that of the inflorescence as a whole, the flower itself being always small and, as a rule, dull in colour—but their greatest claim to our notice rests in the beauty of their foliage. Whilst this is, in many instances, remarkable for its size and form, it is, above all, to its rich and often brilliant autumn colouring that the great value of the hardy Sumachs as ornamental shrubs is due. Those that are hardy in Britain resolve themselves into two distinct groups. The first of these contains two species, viz., *R. Cotinus* and *R. cotinoides*, which are distinguished mainly by the leaves being undivided. Some authorities make a separate genus of them. The other section contains the more numerous species that have either trifoliate leaves (like *R. Toxicodendron*) or pinnate leaves (like *R. typhina*). Most of these latter species with compound leaves bear male and female flowers on separate plants. The common name of "Sumach" is derived from "sumac" or "shumac," which is a dye made of the powdered leaves of *R. Coriaria*. Large quantities are imported annually to Britain, mostly from Sicily.

In writing of the Sumachs, it is necessary to call attention to the poisonous properties that belong to at least two of those here mentioned. These are *R. Toxicodendron* (or *radicans*) and *R. venenata*. The juice of these species when applied to the skin is a very strong irritant, and although a few people can handle the plants with impunity, on the majority the effects are

very painful, occasionally even dangerous. A correspondent to a contemporary a few weeks ago asked if the poisonous action of these plants was a myth. It is a very real thing. At least half a dozen cases have come to my personal notice. As a rule it is in propagating or in pruning that the mischief is done. The sap

runs on the hands and is afterwards transferred to various parts of the body; a few hours after, this is followed by inflammation and an intolerable itching, and ultimately by eruptions or even ulceration. It may be months or even years before the effects finally disappear. Zinc ointment appears to be the best palliative for the itching, but the eruptions apparently have to run their course. Unless a person knows himself to be safe from the effects of the juice of these plants, gloves should always be used in handling them.

As regards their cultivation, the Sumachs may be described as very accommodating. Any soil that is of moderate quality will suit them. They certainly do not need a very rich soil, and they bear prolonged drought better than most things. Most of them can be propagated by root-cuttings and others root readily from layers. Some of the species are naturally short-lived. This is a list of the species dealt with in the following notes, together with the commonest synonyms:—

EUROPEAN.—*Cotinus*, *Coriaria*.

CHINESE AND JAPANESE.—*Osbecki* (syn., *R. semialata*), *trichocarpa*, *Toxicodendron* (syns., *R. radicans*, *R. ternata*, *Ampelopsis japonica*, *A. Hoggii*, *succedanea*, *vernifera*).

AMERICAN.—*Aromatica* (syn., *R. canadensis*), *copallina*, *cotinoides*, *glabra*, *Toxicodendron* (also Japanese), *typhina* (syn., *R. viridiflora*), *venenata*.

RHUS AROMATICA.—From the other hardy species of *Rhus* this differs in its habit of flowering in spring before any of the leaves have begun to show. It is a bush of rather low, straggling habit, not often seen more than 3 feet to 5 feet high. The leaves consist of three leaflets, each leaflet being

soft pubescence (more especially when young), and irregularly toothed; the middle one is the largest, and is itself sometimes three-lobed. When crushed the leaves emit a slightly aromatic scent. The juice is not poisonous. The flowers are pale yellow, and are produced in short, dense clusters, which are formed in autumn, but do not open till about the middle of the following April; they are followed by fruits about the size and colour of Red Currants. It is a native of the Eastern United States, and was introduced in 1759.

R. A. VAR. TRILOBATA is a smaller-leaved variety found in Colorado and other Western States. Its leaves are smaller, and the leaflets are distinctly lobed towards the apex. The odour of the foliage differs from that of the type in being more unpleasant.

R. COPALLINA.—Sargent observes of this species that in America its foliage is more beautiful in summer and autumn than that of any other North American Sumach. It scarcely bears out that character in this country, although certainly a handsome shrub. From the other American pinnate-leaved species it can at once be distinguished by the leaf-stalk being winged between the leaflets. In the Southern United States it appears to be sometimes a fair-sized tree (25 feet to 35 feet high), but it is only a shrub in the more northern parts, and with us never more than 5 feet high. The leaflets, of which there are generally nine to thirteen, are each 2 inches to 2½ inches long, bright dark green and smooth above, pubescent beneath. In autumn they turn a dark brownish crimson. The flowers are borne on broad, dense, terminal racemes, but have no particular beauty. The different sexes are on separate plants. It was introduced in 1688, and was cultivated by Compton, Bishop of London, at Fulham. It does not furnish any of the copals of commerce, as the name might be thought to imply.

R. CORIARIA, the species that furnishes the sumach of commerce, is a native of South Europe. Loudon includes it among his hardy

The Smoke Plant (*Rhus Cotinus*).

Sumachs, and states that it was introduced in 1629, but I have not yet met with it. Some con-

tinental nurserymen offer it for sale, but we have never been supplied with the true plant—generally with *R. typhina*. I suspect it is not hardy.

R. COTINOIDES (Chittam Wood).—I know no Sumach, nor indeed any shrub, that assumes beautiful autumn tints more regularly than this. Whatever the season may be, wet or dry, cold or warm, its leaves become a beautiful scarlet, suffused with various shades of orange and crimson. I have never known it fail. At present it is one of the rarest American shrubs in this country, and what is generally supplied for it is the common Venetian Sumach. It is a native of several of the Southern United States, but even there is very rare. It was originally discovered by Thomas Nuttall in 1819, on the banks of Grand River, a tributary of the Arkansas. Long after, it was again found on the Cumberland Mountains, in Alabama, and subsequently in Tennessee and in Texas. Professor Sargent observes that “during the War of Secession nearly all the large specimens were cut down for the dye which the wood yields. The tree is much less common than formerly and is in danger of extermination.” It bears a strong resemblance to our European *R. Cotinus*, the leaves being quite undivided and entire, but larger and not so round as those of its ally. It is also of more open, less bushy habit, and apparently gets to be a larger tree than *R. Cotinus*, for Sargent describes it as “a small tree, occasionally 25 feet to 35 feet high, with a trunk 12 inches to 14 inches in diameter.” The flowers are also borne on longer and more slender panicles, but it has not yet, so far as I know, flowered in Britain. It is, however, as one of the most lovely of autumn-tinted shrubs that it deserves to be widely known. It was introduced to cultivation through the agency of the Arnold Arboretum in 1882.

R. COTINUS (Venetian Sumach, Burning Bush, &c.).—Aiton says that this shrub was introduced in 1656, but in spite of that and its great beauty and the fact that it thrives well in even poor soil, it is by no means very extensively planted. In a wild state it is generally distributed over Middle and Southern Europe, and extends thence to the Orient, Caucasian region, Cashmere, the Himalaya and China. The leaves, which vary from 1 inch to 3 inches long, remain on the plant into winter, and before they fall often turn a rich yellow. The great beauty of the Venetian Sumach, however, is in its curious inflorescence. The flowers are borne on a broad, much-branched panicle, many of whose final sub-divisions are flowerless, and reduced to mere thread-like stalks, which are clothed with fine hairs. It is during August that these remarkable panicles are in their greatest beauty. They have then become like tufts of down and have put on a beautiful deep flesh colour. Although usually a shrub not more than 6 feet to 8 feet high, spreading out, however, twice as much in diameter, the Venetian Sumach is found wild sometimes as much as 12 feet high, almost a small tree. The wood, which is yellow or greenish, is used in cabinet-making and in turnery. The young twigs also furnish a fine yellow dye, much used in dyeing calico, &c. There are two varieties of this *Rhus* in gardens: (1) *atropurpurea*, whose leaves, young wood and panicles are purple, and (2) *pendula*, which has drooping branches.

R. GLABRA (Smooth Sumach).—The only species with which this is likely to be confused is *R. typhina*, and it is easily distinguished from that by the wood and leaves being always devoid of hairs and by the leaflets being more or less glaucous beneath. Neither is it so big a plant, being a shrub rather than a tree, varying from 3 feet to 8 feet high. It does, however, resemble *R. typhina* in the size and character of its leaves, also in the inflorescence. It is rather curious that while the other parts of the plant are smooth, the flower-panicles, the flowers themselves, and, in the female plants, the fruits, are covered with crimson hairs. The fruiting panicles are especially handsome and they retain their beauty right into the winter. The leaves die off a fine rich red as in *R. typhina*. The species is a native

of the Eastern United States and was introduced in 1726. The

VAR. LACINATA is very distinct, the leaflets being longer and of much greater breadth than in *R. glabra* itself, but they are cut up into narrow, more or less pinnate segments. The engraving gives a very good idea of the feathery grace of a well-grown plant.

R. OSBECKI.—Just as *R. copallina* can be distinguished from the rest of the American Sumachs by the leaf-stalk being winged between the leaflets, so can this species be recognised among the hardy Asiatic ones by the same character. Its foliage is, however, more striking than that of *R. copallina*, the leaves being much larger. Each one consists of five or more pairs of leaflets, some of which on especially vigorous shoots will measure 6 inches long by 4 inches to 5 inches broad. The leaves are, indeed, as regards size, the most striking among those of the pinnate-leaved Sumachs, and the species is worth growing for this character alone. When grown for this purpose the shoots should be pruned hard back each spring, and the new growths reduced to one or two on each. The leaflets have their margins set with large blunt teeth, and the under surface is covered with a close, pale-coloured wool. In suitable seasons they turn orange, or orange-scarlet, in autumn. The flowers are produced on large terminal panicles in July and August, but have no special attractions. The species is a native of China and Japan, where it gets to be a tree 20 feet high. It is sometimes regarded as one of several varieties of *Rhus semialata*, a species widely spread over North-east Asia, which has these winged leaf-stalks.

R. STUCCADANEA.—Unfortunately, this species, which is one of the handsomest of the Sumachs, is not quite hardy in most parts of Britain. Its pinnate leaves are a soft rich red when young, and turn the same colour again before they fall in autumn. Near London it can only be successfully grown in pots and housed during winter. It has been grown in the temperate house at Kew for many years. Possibly the confinement of the roots in pots tends to heighten its colour. It is certainly worth growing for this quality alone, and would most likely thrive outside in the south-western counties. It furnishes the Japan wax which is used, although not so much as formerly, in candle-making.

R. TRICHOCARPA.—It is only quite recently that this Sumach has been introduced to cultivation, and it is too soon to say anything definite as to its value in gardens, but the following extract from Sargent's *Forest Flora of Japan*, describing it as it appears in its native country, leads one to hope it may thrive here: “It should be cultivated for the extraordinary beauty and brilliancy of the leaves in autumn, when they assume the brightest scarlet and orange tints. It is a slender tree, sometimes 20 feet to 25 feet high, and very common in the forests of Yezo and on the mountains of Central Hondu. The leaves are 18 inches to 20 inches long, with dark red midribs and broadly ovate, long-pointed leaflets, slender panicles of flowers, which open in July, and pendulous fruit clusters with large, pale, prickly drupes ripening in August or early in September. Neither the flowers nor the fruits are attractive, and there is nothing very distinct in the appearance of the tree except in autumn, when, however, it is so beautiful that if it succeeds here I believe it will prove one of the best introductions of recent years” (p. 33). Young plants have already coloured well with us.

R. TOXICODENDRON (Poison Ivy).—In a state of Nature this is the most widely spread of all the hardy species of *Rhus*, being the only one that is a native of both the eastern and western hemispheres (North America and Japan). In gardens it is the species most grown, although often under a variety of names. The commonest of these is *Rhus radicans*; other more misleading ones by which it is known are *Ampelopsis japonica* and *Ampelopsis Hoggi*. The species exists in two distinct forms—as a shrub and as a climber. Between these, however, there come

more or less intermediate forms. Even the shrubby one is of somewhat rambling habit. The other is a distinct climber, emitting aerial roots like an Ivy. In the forests of Japan it climbs to the summits of the largest trees. Both the forms have leaves composed of three broad-oval leaflets, which are mostly entire at the margin, especially in the climbing plant, although sometimes set with a few coarse teeth; they are stalked, and the blades vary from 1½ inches to 6 inches in length and are generally more or less woolly. In autumn the leaves turn a very fine purplish red, the Poison Ivy being a plant that very rarely fails to colour well. Both the forms were originally introduced from the Eastern United States. The poisonous nature of the plant has been already alluded to. It is best not to plant it close to paths or in places where trimming with a knife may frequently have to be done. Although so poisonous in its effects on the skin of most people, it is curious that animals eat the foliage without any ill-effects.

R. TYPHINA.—The Stag's-horn Sumach, as this is called, is one of the finest of the species with compound leaves. It is a native of the Eastern United States, and has been cultivated in England since the time of King James I. It was one of the plants grown by Parkinson. Here it forms a small, round-topped tree upwards of 20 feet high. In America Sargent states that it is occasionally twice as high as that. When cut, its wood quickly exudes a thick yellowish juice, which is not poisonous. The wood on the younger branches is always hairy, which affords a ready means of differentiating this species and *R. glabra*. The leaves vary in size according to the age, vigour, &c., of the plant. On mature trees they will range from 12 inches to 18 inches long; on young hard-pruned specimens, 2 feet to 3 feet long. The numerous leaflets are toothed, lanceolate, 3 inches to 6 inches long, and when they first open are covered beneath with reddish hairs. During the summer they are deep green, but in autumn if the season is suitable they turn a brilliant red, sometimes suffused with crimson or orange. Male and female flowers appear on separate plants, and the variety known as *viridiflora* is simply the male. In both sexes the flowers are densely borne on hairy panicles, but the female panicles are shorter and very compact. The flowers, flower-stalks, and fruits are thickly covered with crimson hairs, and the fruits retain their colour through much of the winter. The Stag's horn Sumach is sometimes grown as a subtropical plant, being cut back every spring and reduced to one or two shoots, as in the illustration. It then forms immense leaves, which are especially ornamental in autumn.

R. VENERATA (Poison Sumach).—The juice from the stems of this species is equally, if not more poisonous than that of *R. Toxicodendron*, and, being more uncommon and not well known in gardens, it is the more necessary to make known this character wherever the plant is grown. In other respects it bears but little resemblance to *R. Toxicodendron*. It is a shrub whose pinnate leaves consist, as a rule, of about eleven leaflets, which are each 1½ inches to 3 inches long, glossy, smooth (except when quite young), and have the margins quite entire. In autumn they are singularly beautiful, turning a brilliant scarlet. Loudon describes them as being at this season “of unparalleled splendour.” The plants are unisexual. The female ones fruit occasionally in England, the berries being the size of small Peas and hanging in graceful clusters from the leaf-axils near the ends of the branches. The species is a native of the Eastern United States, where it is sometimes met with over 20 feet high, and whence it was introduced early in the eighteenth century. Judging by the situations in which it often grows in Nature, it is likely to be more moisture-loving than most of the Sumachs.

R. VERNICIFERA is the famous Lacquer Tree of Japan, of which country it is not, however, thought to be a true native, although it has been extensively cultivated there for many hundreds of years. It is certainly a native of China,

although, according to Dr. Henry, it only grows wild in the mountainous districts. The pinnate leaves are large and striking, the leaflets being entire and covered beneath with a velvety wool.

Rhus glabra laciniata.

It has grown well and survived the last three winters at Kew, but whether it will survive our hardest winters is perhaps doubtful.

Arboretum, Kew.

W. J. BEAN.

TREES AND SHRUBS CERTIFICATED DURING 1898.

THE number of hardy trees and shrubs that have received either first-class certificates or awards of merit during the year 1898 is just the same as last, viz., nineteen—that is, if the hardy Bamboos are included in the list. The most notable feature this season is the number of these Bamboos that have been thus honoured, for no less than six obtained recognition from the committee, the occasion being the special exhibition of these plants held at the Drill Hall on July 26. *Ligustrum Walkeri*, which received a first class certificate on September 20 and has been the subject of sundry comments since, has not been included, as it must be considered more as a greenhouse than a hardy shrub.

The following is the complete list, the names being given in the same order as they were shown:

AZALEA OBTUSA.—This is one of the small-growing forms of *Azalea*, a good deal in the way of some of Mr. Carmichael's hybrids between *A. amona* and members of the large-flowered Indian section. *A. obtusa* forms a freely-branched little bush and the orange-red flowers are borne in great profusion. There is also a variety whose flowers are generally pure white, though occasionally a few stripes of red may be found on some of the petals. It is a native of Japan, and has been now grown in our gardens for many years. Although it is the *Azalea obtusa* of Lindley, its name, according to the Kew list, is *Rhododendron indicum obtusum*. It is hardy only in favoured localities, but forms a very ornamental plant for the cool greenhouse. An award of merit was bestowed upon it on March 22.

AZALEA J. J. DE VINK.—The hardy mollis group to which this belongs has received many additions of late years, and among the best of them must be included this variety. The flower clusters as well as the individual blooms are

large, the colour being pale orange, suffused with salmon.

DEUTZIA PARVIFLORA.—A native of Northern China, this *Deutzia* was introduced about ten years ago, having been put into commerce by M. Lemoine, of Nancy. It forms a sturdy bush that will reach a height of 4 feet or 5 feet, being altogether a stouter growing plant than the popular *Deutzia gracilis*. The flowers, which are arranged in small flattened corymbs on the shoots of the previous year, are white and much like those of the Hawthorn. It is quite hardy, and in the open ground flowers a few days earlier than *D. gracilis*. These two species were crossed by M. Lemoine, the product being *D. Lemoinei*, which rapidly became popular, and received a first-class certificate in the spring of 1896.

AZALEODENDRON EDOUARD ANDRE.—The botanical certificate which was awarded this plant on April 26 is the first, as far as I know, that has been bestowed upon any of our hardy shrubs for a very long time. It is certainly an interesting hybrid, having been raised from *Azalea mollis* crossed with a variety of *Rhododendron ponticum*. Though curious, it is not particularly ornamental, the flowers being pink with crimson spots on the upper petals.

ILEX GOLDEN KING.—Among the numerous green-leaved varieties of Holly a very popular kind is that known as *Hodginsi*, characterised by a free, bold style of growth and large, dark green leathery leaves. The variety *Golden King* is a sport from this, and differs only from the type in the markings of the leaves, which have a rich green centre, and are broadly, but irregularly, edged with gold. At the Temple show it received an award of merit.

PHILADELPHUS MONT BLANC.—This is one of the many hybrid forms of *Mock Orange* raised by M. Lemoine, of Nancy, in the production of which the little New Mexican *Philadelphus microphyllus* has played a part. The variety *Mont Blanc* produces its pure white, sweet-scented blossoms when not more than a foot high.

PHILADELPHUS LEMOINEI.—This was the first of M. Lemoine's hybrids from *P. microphyllus*, and though distributed so long ago as the autumn of 1887, it was only on June 28 last that an award of merit was given it, while the previously mentioned *Mont Blanc* received the same award on June 14.

HEDYSARUM MULTIFLORUM.—The subject of a coloured plate in vol. liii. of *THE GARDEN*, and a widely known, low-growing shrub, this *Hedysarum* obtained an award of merit on June 28. It is a somewhat loose, weak-growing plant clothed with greyish pinnate leaves, and during June and July the spikes of pea-shaped flowers are plentifully borne. The colour of the blossoms is a kind of magenta-purple, not altogether a pleasing tint. It is a native of Southern Mongolia, and has been grown in this country about a dozen years.

PICIA PUNGENS GLAUCA PENDULA.—This is a very striking variety of the Colorado Blue Spruce, the older forms of which the late Mr. Anthony Waterer used to grow so well. The branches of this droop in such a manner as to well merit the name of *pendula*. A plant about 9 feet high was sent from Holland by Messrs. Koster, Boskoop, and a first-class certificate awarded it on July 12.

ARUNDINARIA SETIDA.—On July 26 several beautiful hardy Bamboos were submitted to the floral committee, one of the most striking being *Arundinaria nitida*, which obtained a first-class certificate. It is as yet a rare species from Northern China, but will doubtless be much sought after, being an extremely graceful plant. The young shoots are purple, while the bright green lanceolate leaves are borne in such profusion as to quite weigh down the slender twigs. It has proved to be thoroughly hardy, and is in every way particularly desirable.

ARUNDINARIA ARISTATA.—This species occurs on the North-eastern Himalayan ranges in Sikkim and Bhotan at an altitude of about 10,000 feet. The stems, which reach a height of 10 feet or thereabouts, are yellow and upright till bent by the clusters of long, narrow, bright green leaves. In this species the sheaths at the nodes are remarkably persistent.

ARUNDINARIA VEITCHII.—This is a far better-known plant than either of the preceding, but much less graceful in habit. It forms a free-growing, somewhat flat-topped mass a couple of feet or a little more in height. The leaves are large, being over 2 inches wide and 6 inches or 7 inches long. During the summer the foliage is of a fine dark green, but at this season the edges of the leaves become withered and present at a distance a curious feature. Care must be taken

Rhus vernicifera.

in planting this, as the creeping rhizomes are particularly aggressive.

ARUNDINARIA METALLICA.—Concerning this

Bamboo, the well-known authority, Mr. Freeman-Mitford, in an article in the *Gardener's Chronicle*, says: "This Bamboo, recently introduced by me from Japan, is likely to make a valuable covert plant. It is very like *A. Veitchii* in character, but bolder and stronger, and does not wither at the edges in winter like *A. Veitchii*. It has most rampant rhizomes, and is, therefore, not suited for anything but woodland work. In a garden it would soon become a nuisance; in a covert, on the contrary, it is a most beautiful ground plant. Being a native of the coldest districts of Japan and of the island of Yezo, it is perfectly hardy. The name *metallica* is a translation of the native Japanese name."

PHYLLOSTACHYS CASTILLONIS.—This pretty and distinct Bamboo has larger leaves than many other species, as on the more vigorous shoots they are as much as 8 inches or 9 inches long and nearly a couple of inches wide. They are prettily striped with creamy white, while the sheaths of the branches are pink. The stems are very much channelled, owing to the pressure of the branches before they develop, these channels being green, while the rest of the stem is yellow. It is certainly worthy of a place among the best of our hardy Bamboos.

PHYLLOSTACHYS FULVA.—This forms a spreading tuft of gracefully-disposed shoots clothed with long lanceolate leaves dark green above and slightly glaucous beneath. The slender stems are yellow, as in *Phyllostachys* (*Bambusa*) *aura*. It has been recently introduced from Japan by Mr. Freeman-Mitford, by whom it was exhibited. Of the six Bamboos above mentioned, the first, *Arundinaria nitida*, was awarded a first-class certificate, while the remaining five received awards of merit, all on July 26.

BUDDLEIA VARIABILIS.—In the cut specimens shown the leaves were lanceolate, deep green above and whitish beneath. The flowers, which are borne in small clusters, thickly disposed along the points of the shoots for a foot or more, are of a rosy purple tint with an orange eye. In habit, foliage, and flower, however, there are so many individual differences, that the specific name of *variabilis* is particularly appropriate. It is a native of Central China and Eastern Tibet, and is but moderately hardy in this country. It flowers for some time during the summer, and received an award of merit on July 26.

ACER NEGUNDO ELEGANS.—A vigorous form in which the young leaves are heavily margined with clear yellow; the centre, too, is of a pale shade of green. In the mature foliage the yellow changes to a creamy tint, while the green portion becomes more decided. It is quite distinct from the ordinary variegated *Negundo*, and a first-class certificate was given it on September 6.

POPULUS ONTARIO VARIEGATA.—The heart-shaped leaves of this Poplar are deep green, splashed to a varying degree with golden yellow, but though some of the individual leaves are very pretty, as a rule variegated-leaved trees are seldom satisfactory.

ACER JUHLKEI VARIEGATUM.—Much the same may be said of this, which is a form of the North American *Acer dasycarpum*, in which the leaves are irregularly variegated with white. This and the preceding received awards of merit on September 20.

HIBISCUS SYRIACUS TOTUS ALBUS.—Last year the first two varieties ever recognised by the Royal Horticultural Society, *celestis* and *Painted Lady*, were given awards of merit, and this year another must be added, viz., *totus albus*, with pure white single blossoms. It is in no way a novelty and is kept in stock by most of our tree and shrub nurserymen. In any selection of the best varieties of this *Hibiscus*, this pure white variety must have a place. T.

Hypericum olympicum.—It is said of this species on page 492, "It is only hardy enough to withstand our mildest winters." This is a mistake. I have grown it in this cold garden on cold clay soil for more than twenty years, and

have never known it to be killed by cold. Few of the ornamental *Hypericums* are perfectly hardy here, but this is one of the hardiest. It is, however, short-lived; the shrubby base after flowering for two or three years becomes so hard and woody that it cannot break freely, and the shoots get strangled by the imperfect passage of sap from the roots. If not cut down in autumn, I find seedlings come in abundance from self-sown seed, especially on gravel walks if the plant grows near them. These may be transplanted easily when young, and supply a plentiful succession. I daresay this summer I had a hundred flowering plants of this kind in different parts of the garden, mostly left where they came up. The reason of the comparative scarcity of *H. olympicum* in gardens is not its tenderness, but because gardeners do not take the trouble to replace it at the end of its short life, which may be done either by cuttings or by seed. The plants are generally cut down in tidying the herbaceous borders before the seeds are ripe—a mischievous process by which many good plants are lost.—C. WOLLEY-DOD, *Edge Hall, Malpas.*

NOTES & QUESTIONS.—TREES & SHRUBS.

Cotoneaster frigida.—This is not often met with. Recently I saw a fine plant standing near the front door on the verge of a shrubbery at Montacute House, near Yeovil. At the time of my visit there was an immense lot of berries on it. The tree was from 25 feet to 30 feet high.—J. CROOK

Magnolia grandiflora not flowering.—A neighbour of mine has, against the south wall of her house, a beautiful *Magnolia* tree 20 feet high and about twenty-five years old. It has never flowered. The soil is red sandy loam, but the roots run under the gravel walk. Can you suggest what it wants?—JUNIA.

NOVEMBER IN SOUTH DEVON.

DURING the past month rain to the extent of 3.99 inches has fallen on fourteen days. In November, 1897, there were twelve rainy days, on which 1.25 inches fell, while the average for the month is 3.91 inches. In the eleven months of the present year now elapsed 23.83 inches of rain have fallen on 128 days, while for the corresponding period of 1897 the rainfall was 29.12 inches with 152 wet days. The average for the first eleven months of the year is 30.89 inches, and the average for the whole year 34.54 inches, so that with December's rainfall to add we are rather over 10½ inches behind the yearly average. Although November, 1897, was so considerably drier than the past month, it was far inferior as regards its sunshine, only 33 hours 55 minutes being registered against 56 hours 40 minutes in November, 1898, while the average for the month is 61 hours 5 minutes. During the first eleven months of the present year the sun has shone for 1667 hours 10 minutes, the average for the period being 1655 hours, and the record for the similar period in 1897 1627 hours 15 minutes. The 1st of the month was a very sunny day, 88.2 per cent. of the possible sunshine being experienced. The mean temperature of the month, 49.4°, is exactly the same as that of November, 1897, which is rather more than 2° above the average mean temperature of 47.3°. The highest sun temperature was 95.9° on the 1st, the highest in the screen 62.9° on the 16th, the lowest in the screen 30.2° on the 23rd, and the lowest on the grass 26.5° on the same date—the first frost of the winter of 1898-9. On four days the mercury on the grass fell to 32° or below. The total horizontal movement of the wind has been 5545 miles against 6621 miles in November, 1897. The greatest daily run was 579 miles on the 2nd, and the highest hourly speed was attained between the hours of 11 and noon on the same date, when a velocity of 34 miles per hour was registered. On seventeen days the direction of the wind was from south to west. The mean amount of ozone in the air was extremely small, only 40.7 per cent. being registered for the month. On no day was more than 60 per

cent. recorded. The humidity was 87 per cent. against 85 per cent. in 1897.

The autumnal tints have in this neighbourhood been unusually poor in colour, and though some great Beeches showed copper-red towards the middle of the month, their display was markedly inferior to that of former years. By slow degrees the Elm leaves yellowed and fell one by one without affecting the green colouring presented by the remaining foliage; indeed, it is not till the present time, towards the end of the first week in December, that the big Elms in the valley have donned their raiment of light gold, a scanty vestment, for more than half their leaves have already fallen, while their sisters on the hillsides are bereft of all vestige of foliage. In the early part of the month the Virginian Creepers were at their brightest, and it was perhaps merely a suggestion of the imagination that caused one to fancy that their tints lacked something of their usual brilliancy. After the leaves of *Vitis inconstans* had fallen, some walls were almost purple with the crowded berry-clusters. *Clematis Vitalba* (Old Man's Beard) is very beautiful now, many large trees being festooned with its feathery grey trails. From the lofty boughs of a great Ash its swaying stems hang down in a twisted loop like lianas in a tropic forest, while the olive-green foliage of a spreading *Ilex* is wreathed to its topmost spray with the downy seed-vessels. The Spindle Tree berries are past their best, but the scarlet-fruited skeins of the Bryony still hang here and there in the hedges. The swallows and martins did not all leave us in October, for on rainless days a few of both were to be seen, and on the 11th I counted no less than twelve martins hawking, at some height in the air, over one field. The robins and wrens are now much in evidence around the house, and are continually entering at the open windows. Their sweet, subdued songs have a sense of cheery homeliness in their notes that is absent from the elaborate carols of more noted songsters. Wrens are particularly partial to green-fly, and consume an enormous number of these pests. The other day I was watching the actions of a couple of these birds in a large *Chrysanthemum* house as they systematically searched plant after plant for their prey, examining the upper and under sides of the leaves and peering among the petals of the blooms lest a single insect should escape them. A green woodpecker has lately taken to visiting a steep and rather mossy bank, not more than 15 yards distant from the house, every morning shortly after dawn. He is evidently hunting for insects of some description, as he digs his strong beak vigorously into the bank and scrapes the Moss down. He, presumably, has "good hunting," as he returns morning after morning and has already scarified several square yards of the bank. In the middle of the month I saw a handful of very fair Strawberries that had been picked in the open, as well as a few fine Raspberries, while several young Apple trees were bearing rosettes of expanded blossom. On the night of the 27th, about 10 p.m., a sharp thunderstorm, with vivid lightning, broke over the immediate neighbourhood. In some parts there was a deluge of rain for a short time, while in others very heavy hail fell in such quantities that, although there was no frost, some was still visible on Monday night. A good deal of damage was done to Lettuces by the hail, their leaves in some cases being cut to ribbons. During the early days of the month, in a stroll around some neighbouring grounds, I came across, in an open glade, a large specimen of *Spirea Lindleyana* surrounded with numerous self-sown seedlings. There is a large plant of the same *Spirea* in my garden, but no seedlings have ever appeared around or beneath it.

In the garden the Sweet Alyssum was still in blossom at the commencement of the month, and the first flower opened on the bed of Poppy Anemones, while *Aster grandiflorus*, with its large purple flowers, was a mass of deep colour, and *A. Amellus bessarabicus*, that commenced to bloom in August, still held a few decorative flower-sprays. Here and there *Carnas*, that had been

left out so late, showed a spike or two of bloom, but it is generally wiser, except in cases where these can be left out permanently, which happens only in sunny, sheltered spots and in porous soil, to lift at an earlier date, especially where it is the intention to start the plants into growth in March for a summer display in the beds, as a longer period of rest is thereby obtainable than if the plants are left in position until cut by the frost. The dwarf, large-flowered Crozy Cannas should, where practicable, be potted and kept in a slightly moist condition during the winter rather than dried completely off, as their constitutions are not so hardy as are those of the older and more vigorous-habited Cannas. On the railway embankments and rocky ledges the varieties of Valerian (*Centranthus ruber*) still show a few spikes of bloom, pink, white and red. The great Christmas Rose (*Helleborus altifolius*) expanded its first blossom on November 10, eighteen days later than in 1897. A few flowers still remained on *Coreopsis grandiflora* early in the month, and tall plants of *Cosmos bipinnatus* had their Fennel-like leafage thickly set with simple star-flowers of white, pink and intermediate shades, those with white flowers being by far the most attractive. Some of these plants attain a height of over 6 feet and have a branch-spread of between 3 feet and 4 feet. Such should have a strong Bamboo stake driven into the ground close to their main stems early in the autumn, to which the stem can be loosely fastened, in order to prevent the damage which will otherwise occur during October gales. No attempt at staking after the event can be satisfactory, the injury to the sappy shoots being usually too extensive to permit of artistic rearrangement. In sheltered corners Crimms were to be seen in bloom through a great portion of the month, but where exposed to the wind and rain they soon lost their attractiveness. The first frost puts a premature end to the already waning display of the Dahlias. Here and there a few blue flower-spikes, travesties of their summer show, were to be descried on the Delphiniums, while great gold stars appeared at infrequent intervals on the clumps of *Doronicum plantagineum* excelsum. In some gardens *Erigeron speciosus* bloomed well into November, its first appearance having been early in June, a blooming period of five months. The Mexican Daisy (*E. mucronatus*) is an even more persistent bloomer, as, while commencing its flowering period in May, it is still in bloom at the present time in warm, sheltered spots on light soil. *Fuchsia Riccartoni* continued to bloom until the advent of the first frost, and at the commencement of the month a few tall flower-spires of the Cape Hyacinth (*Galtonia candicans*) were here and there to be seen. The Gaillardias continued to bloom sparsely up to the second week of November, and the *Gentianella* to produce an occasional deeply-blue flower, while *Geranium sanguineum* and *G. striatum* were not entirely blossomless. The *Hydrangeas* remained decorative until well into the month, and *Hypericum Moserianum* bore its yellow flowers throughout November. Early in the month the beautiful *Iris stylosa* produced its first fragrant lavender-blue blooms, and has since then been flowering abundantly and affording many an artistic bowlful for indoor decoration. Unfortunately, slugs and snails evince a great predilection for these fair blossoms, which should therefore be picked in the bud state before the petals have commenced to expand. Here and there a solitary glowing flower spike of the *Kniphofia* has been noticeable, and the great bushes of Paris Daisies, which in sheltered situations have not been cut by the frost, are still starred with a few infrequent white blossoms, while some of the *Pentstemons* flowered through the first two weeks of the month. The Winter Cheries (*Physalis Alkekengi* and *P. Franchetti*) showed brightly where they had not been already gathered for arranging in the house, while occasionally the unwonted scarlet of some belated Oriental Poppy flamed inconspicuously from the rain-sodden border. The Tea Roses have afforded a few blooms through the month, sadly washed

out and scentless, however, except when gathered from sheltered walls. The single blossoms of the white Macartney Rose, on the other hand, have not suffered so from the effects of the weather, and have expanded at intervals throughout the month, and this morning (December 5) I picked a perfect half-opened bloom. Late seedlings of *Scabiosa caucasica* have borne their pale blue flowers, while in the earlier portion of the month the Winter Flag (*Schizostylis coccinea*) on warm, elevated borders bore a profusion of its vivid crimson flower-scapes. In a sheltered corner I saw a specimen of the African Hemp (*Sparmannia africana*) bearing great clusters of its white, golden-anthered blooms. The Winter Daffodils (*Sternbergia lutea*) continued their October display, producing their golden Crocus like blooms in quantity, and the purple *Stokesia cyanea* was still flowering early in November. The Vines, single and double, have been in bloom, and the Violets are bearing their scented blossoms, but far more chary than was the case during the corresponding month of 1897. An occasional untimely ivory-white flower-spike was to be seen on plants of *Yucca gloriosa*, and a few brilliant vermilion blossoms were left on plants of *Zauschneria californica*, which, however, have not flowered so abundantly this year as has been the case in former seasons. This plant appears to be a rather capricious subject, sometimes entirely refusing to grow, or, if it grows, to flower, even when soil and situation seem eminently suited to its requirements, and at other times growing like a weed and flowering profusely under apparently unsuitable conditions. Probably a sunny position in the rockery and a soil of sandy loam should meet its wants as well as any that can be suggested, while a site on the level ground and a soil that is heavy and adhesive would not be considered most conducive to its successful culture; yet I have seen it growing vigorously and flowering profusely under the latter conditions, while I have known it refuse to flower under the former seemingly more favourable ones. Several annual flowers, amongst which may be mentioned *Eschscholtzias*, *Stocks*, *crimson Linums*, *blue Cornflowers*, and annual *Chrysanthemums*, added their quota to the meagre floral display of November.

In Mr. Archer-Hind's garden at Coombefishaere several *Crocuses* have been in flower, the most notable of which at the time of my visit were *C. pulchellus* and *C. p. albus*, *C. Curtwrightianus* *albus*, *C. levigatus*, *C. ochroleucus*, *C. Tourneforti*, *C. tingitanus*, and *C. sativus*. The pale yellow *Gladiolus tristis*, of which I wrote in my April notes, had thrown up strong leafage considerably over a foot in height, and numerous seedlings are coming up around the clumps. This *Gladiolus* is not the *G. tristis* (*Botanical Magazine*, 272) which is probably identical with that illustrated on page 391, vol. lii. of THE GARDEN, although the ground colour is given as white-green in the first instance and lemon-buff in the second, but is *G. tristis* (B.) *Bot. Mag.*, 1098. At the commencement of the month *Cobaea scandens* was still blooming, as were *Tropaeolum tuberosum* and the climbing scarlet *T. Lobbianum*, but none of these withstood the effects of the first slight frost. A few flowers still remained on *Eceremocarpus* scaber in the early days of November. A fine specimen of *Abutilon vexillarium* was in full bloom against the house, whilst during the early part of the month *Convolvulus Caeorum* had been covered with blossom. *Iris cretica* as well as *I. stylosa* had commenced to flower, and *Senecio pulcher* was bright with bloom, while a large plant of the blue-grey *Vinca acutiloba* was coming into profuse flower.

TREES AND SHRUBS.

But few flowering shrubs have been in blossom. Here and there the Mexican Orange Flower (*Choisya ternata*) has been bearing the remnants of a second crop of bloom. *Colletia cruciata* has had its spiny branchlets covered with minute white blossoms, and the crimson berries of *Cotoneaster microphylla* begin to show more clearly amongst the dark foliage, while *Cytisus fragrans* may be seen,

in some sheltered nook, furnished with a scanty supply of golden flower-racemes. The *Habrothamnus* still bears its crimson bloom clusters, and the double Jew's Mallow (*Kerria japonica* fl. pl.) bears its orange-tinted flowers against a cottage wall. The *Laurustinus* blooms are gradually assuming whiter discs and many of the shrubby *Veronicas* are flowering, while the great standard Magnolia tree, which expanded its first fragrant white chalice on June 15, produced its last of some hundreds on November 22. *Jasminum nudiflorum* did not commence its period of bloom before the middle of the month. The orange fruits of the Passion Flower are particularly decorative, a larger number than usual having developed during the past autumn, some old plants that have spread their foliage over the entire fronts of houses being thickly strung with the gleaming ovals. *Solanum jasminoides* has flowered throughout the month, and, being sheltered by the eaves of the house, received no damage from the frost. Since the first white bloom-cluster opened in April it has flowered uninterruptedly and profusely until the present time, and bids fair, should no harder frosts supervene, to remain in flower till mid-December or later. S. W. F.

CHRYSANTHEMUMS.

NOTES ON CHRYSANTHEMUMS.

On the whole, notwithstanding the rust, the *Chrysanthemum* season now drawing to a close has been a fairly good one. In the various sections some few varieties have stood out from their fellows as being particularly good. Among those which have been the best of those grown for large flowers are *Pride of Madford*; *Mrs. F. A. Bevan*, a fine addition to the flesh-tinted varieties; *Matthew Hodgson*, a well-formed true Japanese, crimson-chestnut in colour, the best of those which have flowered here for the first time this season; *Joseph Chamberlain*, another fine crimson; *Belle Mauve*, a lovely flower, whose only fault is that of having a weak stem; *Oceana*, a fine incurving Japanese with rather broad petals, the colour a clear butter-yellow; and *Sunstone*, an incurved Japanese, a good flower, but with me the petals were much addicted to dauping. *Mrs. H. Weeks*, one of the very best whites when seen in good form; *Commandant Blusset*, very striking in its deep carmine-like colour, and of good form; *Khama*, one of the best of the crimson-chestnut coloured varieties, always a good grower, but rarely seen at shows as it is rather late in flowering; *Edith Tabor*, well known; and *Australian Gold*, a good pale straw-coloured flower, have also been first-rate. Of old varieties good this year are *Edwin Molyneux*, *Golden Gate*, *Mme. Marius Ricoud*, *G. C. Schwabe*, *Eda Prass*, and *Charles Davis*. *Mme. Carnot* and *Good Gracious* may be put down as quite the failures of the season, but, curiously enough, both the yellow and the primrose coloured sports from the former have been seen in the neighbourhood in grand form.

The useful varieties which adapt themselves to the bush form of growth, and especially those which produce erect and good sprays for cutting, are on the increase and are being better looked after by those who have much cut-flower work to do, and who find out that those only which assume such a habit, under good culture, are of much service. Good varieties of this type include some of the oldest as well as some of the newest of *Chrysanthemums*. The increase in popularity of these decorative varieties has induced the schedule committees of various societies to include classes for them in their schedules, and this is a step in the right direction, especially when the exact number of

sprays admissible is stipulated, for by this means it can easily be seen which are the best and the most economical for growing in spray form. The best I have found up to date are Clinton Chalfont, Source d'Or, Golden Gate, E. G. Hill, Challenge, Aigle d'Or, M. Garnier, Mrs. Filkins and Mrs. James Carter, among the yellow and pale bronze varieties; L. Canning, Fleur de Marie, Mrs. Cullingford, Boule de Neige, Niveum, and Florence Piercy, among the whites; Tokio, Wm. Holmes, Val d'Andorre and Black Hawk in crimsons and chestnuts; Cottage Maid, Roseum superbum, Mme. Marius Ricoud, Mme. de Sevin, Commandant Blusset, and Marie Stuart in varying shades of lilac. Yellows predominate, and this is probably the most useful all-round colour. A word, in passing, as to L. Canning. Many fail with this, but if grown on two-year-old plants it is still the best late white in existence for sprays. Tokio remains the best crimson for those who are content with small flowers. From a large collection of singles, I select the following as being the best, but I may add that seedlings have added to this class some very good things, and as I find that seedlings in their first year flower later than do plants propagated from cuttings, a batch of them is well worth the trouble of growing, even though nothing better than those in stock before is raised. It is pleasing to see how single Chrysanthemums are rising in public estimation, and it is not to be wondered at, for, given clear and distinct colours, no others have quite the same light and graceful effect when used in a cut state. A good many of the older ones have been weeded out either from their washy colours or from faults of habit. Of whites, Mary Anderson, Virgin Queen, Snow Wreath, Snowdrift, and Mrs. A. E. Stubbs (creamy white); of yellows, Kate Hawthorne, Buttercup, and Miss A. Holden, the last a yellow sport from Mary Anderson; of crimsons and chestnuts, Miss Crissy, D. Windsor, and Annie Tweed; and of pinks and lilacs, Emily Wells, Prolific, Mrs. D. B. Crane, and Best of All, a very late variety. I find the best.

J. C. TALLACK.

Chrysanthemum Matthew Hodgson.—There are so many white and light-tinted blossoms among the Japanese forms usually exhibited in a cut state, that bright-coloured flowers attract attention not only by reason of their own merit, but also from the fact that they stand out in a decided manner from their associates. Such an one is Matthew Hodgson, which at the Aquarium on December 6 was one of the most conspicuous varieties exhibited. It was, I believe, raised by Mr. W. Seward, of Hanwell, who has given us so many beautiful forms. Earlier in the year the variety Matthew Hodgson produces blossoms of a rich crimson hue, but the majority of those shown were, from the lateness of the season, somewhat paler than usual.—T.

Rust on Chrysanthemums.—The reply to Mr. Tallack concerning the method employed by Mr. Wythes to free his plants of the so-called rust will, I fear, not prove a very instructive one. It was clearly stated in the notes that a few specks had appeared and were as promptly destroyed. In other words, the moment it was detected careful search was made and the leaves collected and burnt. As no further trouble was experienced, it may be assumed the attack was either a very slight one or that the fungus was detected early enough to prevent its spread by means of mature spores. The affected plant was a recent addition. When the notes were taken at Syon the entire collection was in perfect health and enjoying complete immunity from any disease. This was apparent on the first view by the fine vigour and general condition of the plants,

and abundantly supported by the splendid display of blossoms. As previously stated, Mr. Wythes is a great believer in soot-water for syringing, &c. How far this was an influence for good would be difficult to determine.—VISITOR.

Chrysanthemum shows in Italy.—That interest in the Chrysanthemum is steadily increasing in Italy there can be no doubt, and this is very largely due to the enthusiasm of Mr. H. Briscoe-Ironside, who has been resident on the banks of the Lago Maggiore for some years. Italian nurserymen and gardeners are now busy raising new seedlings, and of these M. A. Scalandis, gardener to the King and the president of the new Italian National Chrysanthemum Society, is one of the leading lights. During the past season shows have been held at Milan, at Turin, and also at Pallanza. The Turin show was a great success, and pot plants were largely shown. On the first day the King and Queen paid a visit to the show, and the greatest enthusiasm appears to have been excited. There was also an exhibition at Pallanza, and both at this and the one preceding Mr. Briscoe-Ironside was a successful exhibitor and prize-winner.—C. H. P.

Pretty little Chrysanthemums.—A small group of Chrysanthemums, great favourites of mine, are those with thread-like petals, of which Mrs. J. Carter is one of the best known examples. It is well adapted for growing in bush form, and where cut flowers are in demand this variety is one of the most productive we have, there being so much of the cut-and-come-again character about it. The colour is a kind of pale sulphur-yellow. There is another form somewhat in the same way as this, viz., Alice Carter, the flowers of which are reddish brown and yellow. In Mrs. Filkins the flowers are of a bright yellow colour, quite distinct from either of the preceding. A large quantity of a white variety, Annie Harvey, was shown at the meeting of the National Chrysanthemum Society on December 6, and a goodly show it made. Mrs. W. Butters, too, is a pretty white not far removed from this class, while quite distinct from any of the others and a great favourite for cutting is King of Plumes, a rather solid flower, but with the points of the florets notched and slashed, thus doing away with any formality. This variety is of good free, sturdy growth, while the colour is an intense rich golden yellow, extremely effective. For furnishing vases and such purposes it is one of the best.—T.

Chrysanthemums in the open.—The absence of frost has been favourable to early-flowering Chrysanthemums, and first-rate displays have been noted in many places. At Folkestone and Hythe during the middle of November they were particularly noticeable. It is a pity, however, that better kinds do not take the place of many of those seen. Thus the dull purple-coloured Lyon filled big patches in many instances, and the Christines, reflexed forms in white, buff, and pink, were very much in evidence. In several gardens Source d'Or was flowering abundantly, and this one good sort stood out most effectively among other indifferent kinds. There is plenty of material in this class now to provide most of the shades of colour required. In whites we have Mme. Desgrange and Lady Fitzwygram. Good yellows are G. Wermig, Orange Child, and Flora, the last a small bloom, but very effective in a mass. Pink is supplied by the varieties Mme. Marie Masse and O. J. Quintus. Mme. Eulalie Morel has blooms of a pretty cerise shade. In bronzes we have Ivy Stark, M. Dupuis, Comtesse F. de Cariel, and the somewhat late-flowering Rycroft Glory. For dark colours, select Ambroise Thomas, Harvest Home, Roi des Précoecs, and Coral Queen.—H.

NOTES AND QUESTIONS.

Chrysanthemum Soleil d'Octobre.—This variety, which was introduced last year, is a distinct addition among yellows. The colour is soft and bright, the growth dwarf and sturdy. It produces

immense blooms when disbudded, and being so free bears an immense quantity of smaller flowers.—S.

Chrysanthemum Australie.—Judged from any standpoint, I think this must be considered the ugliest Chrysanthemum which has been sent out in recent years. Its enormous size has found for it a place on many exhibition boards this year, and I suppose it must for the present be looked upon as one of the "indispensables" for that purpose, but it has positively no beauty whatever that I can discover, and few people would ever take a second look at it for anything but its size.—J. C. T.

GARDEN FLORA.

PLATE 1202.

PLACEAS.

(WITH A COLOURED PLATE OF P. ORNATA.*)

THE genus *Placea* is a small group belonging to the *Amaryllidaceae*, and, as may be gathered from the accompanying plate, is closely allied to *Hippeastrum*. In some points, however, and those of culture more particularly, in so far as the resting and starting are concerned, the *Hippeastrum* may be cited as an example, inasmuch as one special condition in the cultivation of *Placea* is that it must have a complete season of rest. The few species known to cultivators, and which at present represent less than half a dozen kinds, are noteworthy by their peculiar and interesting rather than showy characters. Usually the bulbs are small, not larger than a Walnut, the outer coverings dark and glossy. *Placea* is found at high elevations in the Andes of Chili, and the plants can scarcely be regarded as hardy in this country. But, like many other things from the same locality, the protection required is but little so long as frost is kept off. In these respects these interesting subjects may be cited on a par with *Nerine*, and where pot cultivation is resorted to, may be given almost the same treatment so far as temperature is concerned. Frequently, however, from the unusual depth at which these plants are found in the earth in the wild state, pot culture is not the best for them. Much the best method where a collection of Cape and other bulbs is grown is to set apart a small frame against a hot or sunny wall. By first grouping the plants together in regard to the season of flowering, a difficulty will be overcome which is of vital importance to many of the lovely bulbous things from the localities named, and of which cultivators generally know so little. In this way the resting period as well as the starting may be rigidly enforced, and the depth of planting where this is a necessity likewise adopted. There is, however, no reason why these interesting subjects should not be grown in pots, provided due care be given the bulbs after flowering. One objection to pot culture in the present instance is, that unless a somewhat deep pot is employed no covering, or at least an insufficient one, can be given. Moreover, many similar things delight to have their bulbs on the surface or nearly so, and it is not unlikely that these *Placeas* would be so treated by anyone taking them for the first time in hand. In this respect, however, they differ, and, like the *Narcissi* and other such things, are best suited in this country when buried an inch or two in the earth. Concerning their culture generally Herr Max Leichtlin says:

Placea is one of those bulbs which will not be pot-bound. I either plant them in a walled

* Drawn for THE GARDEN by H. G. Moon in Mr. Perry's nursery at Winchester Hill. Lithographed and printed by J. L. Goffart.

frame which is kept free of frost, or in a low house which has a border on the south side, and is kept at 37° or 40° Fahr. at night, and leave them alone. They go to rest about August and push about December, flowering in May. In a pot they ought to have their exact time of rest, and must be buried in the soil, which ought to be very rich, but in pots they are not certain to flower. They must be planted with at least an inch of soil over their necks, and they prefer a loose soil. I use thoroughly decomposed cow manure (three and four years old), mixed during decomposition with one-third silver sand.

From a circular issued by Mr. Amos Perry, Winchmore Hill, who has this season been distributing a large importation of *P. ornata*, we gather that this species "is found deep in the ground and growing in the most exposed places." One of the chief characteristics of *Placea* is the very distinct though equally perfect evolute corona or cup, in which respect the group more nearly approaches *Narcissus*, resembling the *Hippeastrum* in the divisions of the perianth, these being almost at right angles with the cup. The following are the best members of this interesting group:—

PLACEA AZEÆ.—With pale yellow flowers, lined with purple, and flowering at 1½ feet high when fully established.

P. GRANDIFLORA.—White, striped with crimson, the scape terminating in an umbel of several handsome flowers, leaves long and somewhat rounded.

P. ORNATA.—The kind given in the coloured plate to-day has nearly pure white divisions, each of which is heavily and freely, though irregularly, lined with rich reddish scarlet. The scape attains to nearly a foot high and is said to bear from twelve to twenty of its interesting and pretty flowers. From flowering examples I have seen, however, but which may not be regarded as from established bulbs, the scape was less than 9 inches high and the flowers were about three on the umbel. Doubtless, when well established this number would be greatly increased. I am of opinion, however, that *P. grandiflora* is sometimes imported for *P. ornata*, as my plant, which did not flower this season, is more distinctly related to the former by its more rounded leaves, not unlike those of a small *Narcissus Jonquilla*.

These are the most distinct and at the same time the most deserving of cultivation. Flowering examples of *P. ornata* have this season been exhibited at the Royal Horticultural Society's meetings by Mr. Perry. The same species was also noted in bloom in the No. 7 range at Kew in the early summer. E. J.

Wood ashes.—Of all manures commonly termed artificial, these are, perhaps, the oldest, and as "A. W." has so well shown, still among the best. Burning may not be the most economic way to deal with soft vegetable matter, as in a few months it can be rotted by stacking and moistening. Experience shows that it is very valuable plant food, as all gardeners, especially those whose supplies of animal manure are small, have found to their benefit. In deeply-worked soil splendid crops are commonly produced by the aid, almost exclusively, of decayed vegetable matter. But hard wood broken up ever so small and buried in the soil would be long in decomposing, and would in the process promote much harmful fungoid growth. The conversion of this hard, and, so far as plant food is concerned, useless material into an active manure by burning is a simple process. Wood ashes may not be so rich in potash as kainit, but at least they constitute a singularly safe dressing, not only because of the potash they contain, but because the ash does not immediately dissolve and helps to keep the soil open and friable. No one now advises the making of Vine or other fruit borders without a liberal addition of wood ashes,

and all gardeners alive to their manurial value collect and burn all woody matter not otherwise useful for the purpose. The majority of gardeners agree that we have few artificially produced manures more valuable or desirable than are wood ashes, soot, and lime.—A. D.

THE WEEK'S WORK.

HARDY FRUIT.

BIRDS AND BUDS.—I find that already the Red and White Currants are being attacked by the tit family in a most persistent manner. I do not know if others have observed their propensity for Currant buds to the same extent, and that comparatively early in the winter. During frost and snow there is some excuse to be made for these depredations, but with the mild weather other food should not be scarce. It is the case every year at this time, and often earlier that my bushes are attacked. These depredators are not satisfied with the topmost buds, but go immediately for those at the base, hence the crop for another season is affected if close spur-pruning is resorted to. Last year I was sorely tried by the damage done, so much so that I had to resort to shooting in order to save the trees. This had the desired effect. Sometimes when there may happen to be a store of old netting, this is laid lightly on the bushes. This had the desired effect for a season or two, but the birds became used to it and went under or through the holes. The subject resolves itself into one of two things: either the trees as fruit-bearing subjects must be sacrificed, or the birds, in spite of the Wild Birds' Protection Act, must be kept in check by some means or another. There is beyond any doubt far too much sentiment at present existing upon this subject in favour of the birds. I have tried lime mixed with size and water as well as dilutions of paraffin, but as these are washed off the attack recommences. Fortunately for me, the Gooseberries escape, as the finch family is not over plentiful, neither are these fruits troubled with the caterpillar. All who may have rested, as it were, in the matter of birds and buds will do well to keep their eyes open, for when an attack commences it increases rather than otherwise, as the few which begin the work of destruction are the means of bringing others with them to increase it.

PRUNING BUSH FRUITS.—Various opinions obtain as to the best time for seeing to this work. Some, with the commendable caution born of a desire to leave nothing in arrear, push the pruning forward early. On the whole I prefer to leave it until January, or even a week or two later if the weather be severe. For reasons already given my practice is apparent; in fact, if I were to prune early in the case of the bush fruits I might have cause for regret before the winter was over. One occasion in particular occurs to me even now, when the Gooseberries were laden with snow except the uppermost branches. As the snow lay for a long time the birds became short of food, and in consequence the Gooseberry bushes fell a prey to them. The experience thus gained has served its purpose since. As regards the pruning of Gooseberries, a study of the habit of several kinds will serve a good purpose. The strong growers should not be pruned too very severely, but be treated more upon the extension system by letting them become twice or thrice the size of medium growers. These latter, on the other hand, may advantageously be pruned closer and more upon the spur system. Should any be inclined to grow too strong, a check may be effected by means of the spade when breaking up the ground after pruning. Close spur pruning in the case of most of the Red and White Currants is the best, but there are a few of the largest bunched and berried varieties which bear very freely if treated a little more leniently in the pruning. The time-honoured method of thinning out the old wood of Black Currants is still the best, and if fine fruits are aimed at rather than a greater weight of smaller fruit, it may

even be done more freely still. Should there be any symptoms of the Currant-bud mite, the best plan is to use the knife severely, not leaving any symptoms of it upon the bushes. If this were persevered in, it might be possible to reduce if not to exterminate it. In extreme cases, however, the advice is to uproot them and plant afresh, as it will not pay to have valuable land unproductive. The precaution should, however, be taken of planting the fresh and clean stock as far as it is practically possible away from the infected bushes. Raspberries I prefer to give attention to before the Currants and Gooseberries, as birds in this instance have not to be reckoned with. Guard against overcrowding, not leaving too many shoots to each stool. The best plan I consider is to secure them to wires or stout tarred string in continuous lines rather than in separate clumps, the young growth receiving more benefit in the former than in the latter instance from light and air. There is no real gain in leaving the shoots to an excessive length; it only means more bare stem upon what is otherwise the strongest wood. Where any stools show signs of weakness it will be advisable to thin them more freely, or if very far gone, to destroy them and make up again by dividing the strongest ones. If this be done, see that all such newly-planted stools are well mulched and watered too. The extension system is also the best method of dealing with the choicer Blackberries, notably the cut-leaved variety, which, in spite of novelties much belauded, but of doubtful merit, is still the best, especially for late bearing. After the pruning is completed, take the first opportunity of forking or digging the soil, adding manure with discretion—*i.e.*, if the growth is robust enough and the produce good. A light dressing will be sufficient, for it is simply waste to dress heavily and then, as it were, cart it away again afterwards in superfluous shoots. If a good average dressing of farm-yard manure be applied one season, in another it might be modified by a dressing of either lime or bone-meal. If the Rasperry plantation be in such a position as to suffer from drought during the summer, it will be advisable, in addition to forking over the ground, to mulch it afterwards. In moving some ground only a few days back I noted it was dry in places. If this be the case in any instance, do not hesitate to empty the liquid manure tanks upon the ground the first opportunity that occurs. Even Strawberries upon dry land might be treated thus without any fear of the results.

MULCHING.—The beneficial effects of mulching have been alluded to frequently. The prolonged drought of last summer and early autumn was an instance of the good accomplished by mulching. It may, where practicable, be pushed forward through the winter, especially when the ground is hard enough to bear the weight involved during a frost. Do not omit either to mulch all newly-planted trees, and even if need be water them again. Should the mulch in any instance be deemed unsightly, it can easily be covered lightly with a little soil; in fact, this is a very good practice to follow in trim, well-kept gardens. Another advantage in mulching is evident in shallow soils, where the roots are often nearer to the surface than in deep, rich loam. The roots in such an instance suffer from both drought and cold, neither extreme of which can be beneficial.

BORDERS FOR FRUIT TREES.—In some instances, especially in low-lying districts, the important work of draining, so as to avoid stagnant water, is a factor not readily to be passed over. Over-luxuriance of growth sometimes is caused by this alone, especially where the soil is, in addition, of good quality. During such a dry season as the past has been the roots of many trees have been compelled to descend by reason of want of moisture above. This at the time may not do any harm, but it may do so, however, when a heavy rainfall occurs. Each case, by close observation, should be treated according to its requirements. The concreting of borders in soils of considerable depth, but not of the best fruit-producing quality, will ultimately pay, such, for instance, as in that

of Peaches and Nectarines as well as Apricots in a notable degree. In limited borders the growth can be kept more under control. Successful instances of Apricot culture occur to me at this moment, where by concreting the borders the best results were obtained. The one chief thing to take note of afterwards is to ensure an immunity from drought. It may be urged against this that it involves more labour, but better so than to have unproductive trees. HORTUS.

KITCHEN GARDEN.

GENERAL WORK.—Much may be done now to arrange next season's cropping. I prepare large wooden labels and write thereon the names of crops. The labels are placed in the quarters and at planting or sowing it is only necessary to add the date. By selection of quarters now anyone may better give the most suitable position for the crops. Land infested with wireworm will need special dressing and change of crop also. Ground for early crops should now be ready for the same. It will be well at an early date to clear off any infested crops of Brassica and give the soil a thorough rest from the same kind of crop. It is important to get land turned up to allow the weather to sweeten the soil. Now is a suitable time to select the vegetable seeds needed for another year's supply. The seed lists are now to hand, and the early orders receive the best attention, often getting the kinds needed and not others substituted for those not in stock. To save valuable time at a season work is pressing, I would now advise securing and preparing Bean and Pea sticks needed for another season. In country districts brooms are often made in the garden in wet weather, and a stock of Birch should be cut and then placed under cover. I am now repairing the thatched hurdles, which are invaluable for covering and protecting in the early part of the year. They are more efficient than mats and tidier. The Potato store will need attention where quantities of seed are in stock. For the earliest plantings I am placing the sets in shallow boxes ready for the work. Any sets needed for forcing may be placed in a warm house to induce early sprouting, but it is not well to get growth too much advanced. Globe Artichokes should be given protection in gardens where they die off badly during the winter months. It will not be safe to leave such plants as Cardoons any longer in their growing quarters. They will keep some weeks in a cool store if the roots are left intact. All kinds of roots will now force more readily and regular supplies should be maintained. Avoid hard forcing, as this affects the flavour and causes a weak growth.

FORCING CARROTS.—Carrot seeds require more time to germinate than many others, so that if young Carrots are needed early in the spring it will be well to make up the beds for the same. Carrots do not like hard forcing, and if grown in heated frames they are not always a success. The best roots I ever saw were grown on a mild hotbed. The hot-water pipes with a genial bottom heat will not need much using in mild weather; indeed, I prefer to cover the glass at night in preference to much warmth or dry heat. Leaves are splendid for mixing with fresh manure for forcing vegetables, as the warmth is more regular and lasts much longer. The whole should be made firm to prevent shrinkage, or, what is better, the materials placed in bulk and allowed to heat freely before forming the beds. I fear since the general use of hot-water pipes, growers of the present day have less regard for leaves and manures, but these are much better if slow forcing is carried out, and slow forcing gives superior quality. As regards size of beds and making, much depends upon the quantity needed. There should be sufficient depth of material to ensure enough warmth for some weeks. With the frames on a body of heating materials it is an easy matter to give a good lining round, covering this with loam litter or soil to retain the heat. A fine or light soil should be employed on the surface of the beds, this being placed in position

some time in advance of sowing, so as to get thoroughly warmed through. For frame work I prefer the small stump-rooted kinds, such as the Early Nantes, Parisian Forcing, Early Gem, or any of the Short Horn type. It is a mistake to sow thickly, as the thinning at times is overlooked and the crop suffers. I have obtained excellent crops, but a longer time about, by sowing on beds of warm leaves and covering at night. Grown thus, the beds after the crop is cleared are useful for many purposes.

RADISHES FORCED.—Having large quantities of leaves at this season, I turn them to good account. Much the same remarks apply as to Carrots, but the Radish with warmth germinates so quickly, that two or three crops may be had from the same frame or pit. The Turnip varieties, such as White or Red Forcing, the Olive or Oval Crimson Forcing, and Earliest of All, are specially good. Here less soil will suffice, 4 inches to 6 inches on the heating material being sufficient. Sown now in warmth there should be good roots in six weeks. I find the old Radish beds in frames most valuable for pricking out tender seedlings, such as early Lettuce, Cabbage, Cauliflowers, and such like after raising in heat. The little warmth left in the bed is just sufficient to start the plants. Many sow Radishes with Carrots. I do not advise it, as the Radish often ruins the Carrot crop. If sown in pits, with hot-water pipes to heat the beds, dry heat, or too much, must be guarded against.

FORCING TURNIPS.—For many years I have grown this vegetable under glass, and the demand is quite as great as for Carrots; indeed, more so, as it is a difficult matter to have good Turnips after March; whereas Carrots are fairly good and plentiful. The same mode of culture is applicable as given for Carrots, but once in active growth, more ventilation is needed. It is well to sow close to the glass. Sown early in January, nice-sized roots may be had in three months and at a time there are few sound roots. There are some excellent early varieties for frame culture, the Early Milan being one of the best. There are two kinds of this, the White and Purple, both excellent, as they bulb quickly and grow well under glass if given ample ventilation. A firm bed is necessary, as if at all loose on the surface, the plants have a tendency to run. Thin early and ventilate freely in mild weather, giving ample moisture.

FORCING RHUBARB.—Now is a good time to cover up roots in their permanent quarters, and I am in favour of this mode of culture as the produce is of better flavour than that from lifted roots forced in a warm house. Any material at hand will suffice for covering the roots, but, of course, Rhubarb pots are best if expense is not studied. Needing large quantities, I resort to various means, such as empty casks, which I like better than pots, as they are more roomy. Being much deeper a finer growth is secured, and if the heating material at the start is at all warm, the casks allow the steam to escape more readily. Old cement casks answer well, and in cases where hard forcing is not intended, only a light covering is given to hasten growth. Strong stakes placed round the roots and brought to a point will suffice. In covering, it is advisable to use materials that retain warmth and in sufficient quantities. Roots not intended for forcing early are none the worse for a covering of light litter. These will give earlier growths than those fully exposed. Roots lifted and placed indoors should not suffer from want of moisture, and, if possible, should be damped over frequently with tepid water if the house is at all dry.

MUSHROOMS.—I am a strong advocate of what is termed the cool-house treatment. The splendid crops obtained at Gunnersbury House by Mr. Hudson in unheated underground cellars would convince anyone that my advice is correct. So far this autumn I have not used fire-heat, and the supply has been better both in quantity and quality also. A night temperature of 55° with 5° to 10° higher by day in mild weather will be sufficient. Materials will have needed to be prepared under cover owing to heavy rains, and,

if possible, new beds should be made every three weeks or monthly. Far better make small beds frequently than allow the fermenting materials to get overheated. To prevent this I use it in a more strawy condition and also add a little loam, which retains warmth and assists in making the beds more solid. Old beds will be benefited by giving warm liquid manure from s tables, adding little salt to the liquid. S. M.

ORCHIDS.

ANGRÆCUM SESQUIPEDALE.

Most growers are acquainted with and admire this singularly beautiful plant, with its large white waxy-looking blossoms and their attendant spurs from which the plant takes its name. The growth of this species is quite distinct from that of any other known kind, and when in good condition, either in or out of flower, it is an ornament to any collection. The chief requisites are a strong heat and abundant light, and though growth is perhaps more free in a house with ample atmospheric moisture, it is none the less true that the plant thrives in a drier house than many similar species, and may be placed in dry corners unsuitable to other plants without suffering in any way, provided due attention is given to other details. When newly imported the plants are often sorry objects indeed and as shapeless as they are rough and dirty. But care in potting and staking, pulling the growths into shape and tying make a great difference, while as soon as new growth shows itself the plants have quite a different appearance. Like many other single-stemmed Orchids, it is greatly dependent upon the roots. These, then, must be carefully preserved, and the most likely way to keep them alive over a long series of years is to treat them as they are doubtless treated in their native habitat. Here they cannot always be wet alike, but a great many must be dry for the greater part of the day. For this reason I like to see the roots pushing about in all directions from the central stem, not all confined to the compost, for if some are on the outside of the pot, others, perhaps, clinging to the stage and fully exposed to light and air, they will not all be wet like those in the compost after this is watered. If it were possible, I believe the roots of all Orchids would be better for a few hours' drying, say once or twice a week, but this is not easy to bring about—in the case of large specimens at any rate. Fine plants of this *Angræcum* may be reared in baskets of quite limited size, provided the roots are allowed to ramble as described, and this is a good way to grow it. The plants may also be grown in pots on the stage. In either case plenty of rough pottery ballast and charcoal should be mixed with clean newly-gathered Sphagnum Moss for compost, and the drainage will need special care. It takes disturbance so badly, that it ought not to be repotted oftener than is absolutely necessary. The surface compost may be renewed from time to time and fresh substituted, and if this is done, plants of fair size may go on for four or five years at least with no further trouble. Despite what is said above, *Angræcum sesquipedale* is a very thirsty subject when growing freely, and not only does it like root moisture in abundance, but the tops also may be freely syringed with advantage. The shape of the leaf at the axil is rather singular, and seems specially intended to throw off superfluous moisture, so there is no fear of damping, unless, of course, the treatment was continued in wet or dull weather. The plants are singu-

larly free from insects as a rule, and occasional sponging with tepid water in which soft soap has been dissolved will prevent an attack of scale, the only one that need be much feared.

H. R.

Sophrontitis cernua.—The habit of the species is very dwarf, but the flowers are very distinct and pretty, lasting a long time in good condition. About three are usually produced to each bulb, and these are bright red with a yellow base to the lip. Under cultivation it does well in small pans or on blocks, and it should be kept well up to the light in the cool house. It is a native of Rio de Janeiro, and was introduced in 1826.

Odontoglossum Rossi rubescens.—This is a bright and pretty form of a remarkably useful Orchid, and one that should be looked after. The sepals and petals are tinted with a deep rosy hue and spotted with reddish brown, a pretty combination. The species is one of the commonest, but may be liberally represented in any collection with advantage, for not only are the flowers extremely pretty, but they will last longer perhaps than those of any other species, unless it is *O. maculatum*. Plant in small pots or pans and suspend them from the roof if possible, watering the roots freely all the year round.

Saccolabium bigibbum.—In this species the flower-spikes are only a few inches high, and rather too dense to be as pretty as some others in the genus, but it blooms during a dull season and is very distinct. The habit is dwarf, the spikes push horizontally and are crowded with pale yellow blossoms, the only other colour being some rosy streaks upon the lower part of the lip. It likes a fairly high and very moist temperature, and need only be shaded during the middle of the hottest days. It should be kept well up in the house, and planted in small wooden baskets in clean Sphagnum Moss and charcoal. It is a native of Burmah, and was introduced by Messrs. Veitch and Sons in 1868.

Cypripedium Charlesworthi.—This species has not become so popular as was anticipated, and is another instance of the folly of sending home such vast quantities of any one kind. Many plants are grown, of course, but in all probability the day for any new *Cypripedium* to make a great stir is gone by, as there are so many fine species and hybrids now in the genus. All the same, *C. Charlesworthi* will always be worth growing for the sake of its beautiful flowers for cutting, and this will at least be some consolation for nurserymen who have it in stock by hundreds. The brightly tinted dorsal sepal gives the flower a very fine appearance, and as time goes on it should become a fine useful, warm greenhouse plant, such as *C. insigne*, *C. barbatum*, and others have long been considered.

Masdevallia polysticta.—This is one of the finest *Masdevallias* and a plant worthy of all care. From a tuft of leaves about 6 inches high the spikes are thrown well above the foliage, and these contain half a dozen or so of fine white flowers spotted with purple. It is a robust plant as *Masdevallias* go, and ought not to give even an amateur who is a little experienced among cool Orchids much trouble. Like all in the genus it will not thrive in a dry or overheated house, but when kept cool and moist in summer, and in winter brought well up to the light, it will be satisfactory. Medium-sized pots and a free, open compost with plenty of root moisture all the year round suit it admirably. It is a native of the Peruvian Andes, and is one of M. B. Roehl's discoveries, he having sent it home about 1874.

Odontoglossum cariniferum.—The flowers of this species are produced very freely, and they last well in good condition. They are produced on flexuous, branching stems, and are individually about 2½ inches across. The sepals and petals are olive-brown with yellow margins, the lip white, stained with purple and crimson. It is one of the easiest to grow, and thrives as well in a moderately cool fernery or some such structure as in the Orchid house proper. Fairly strong in

growth and roots, it may be given more pot room than is usually afforded the crispum and similar kinds, a rough and very open description of compost and thorough drainage. It usually rots a short time only, and during this season water must be carefully applied, but in its growing period it is one of the most thirsty subjects. Shade in summer, light in winter, and ample atmospheric moisture are the conditions it likes. It is a widely-distributed plant in Central America, where it was first discovered by M. Warseowicz in the first half of the present century, but if introduced to this country it was rare for a long time after this.

NOTES ON ORCHIDS.

In the cool house, *Odontoglossums* and other Orchids repotted as advised recently have made good progress, and it is interesting to note the effect the new compost has upon the forming bulbs. Not long since, when looking over a fine collection of *O. crispum* and similar kinds, I noticed that many of the plants of medium size only were grown in rather larger pots than usual, and remarking on it to the grower of the plants, a very successful one by the way, was informed that it was his usual practice when the plants had become well established and strong in 3-inch pots to give no intermediate shift between this and a 5-inch pot. Certainly the roots looked as though they enjoyed the freedom given, and a little care in watering afterwards is all that is necessary to ensure their well-doing. Anyone with a few years' experience of this class of Orchid knows well the difficulty of getting small or weak bits to move freely and fill out the small pots in which they are necessarily placed. But once get them beyond this stage and there is every probability they will soon make fine specimens. The rather large shift then in such cases is admissible, as it gives the plants at least a couple of years' grace without further disturbance, and the additional compost strengthens the forming pseudo-bulbs materially. Most Orchid-growing readers will have noticed what an amount of water these newly-potted *Odontoglossums* require to keep the compost moist when the new roots are entering it freely, and unless the weather is distinctly unfavourable, the plants may even yet be watered freely. But when the external air is moist and cold—as it often is at this time of year—both root and atmospheric moisture must be supplied with discretion. Those plants of the *O. grande* section require least now, especially those that have finished flowering, while the plants of other kinds that have not been repotted, and have, therefore, a somewhat closer compost, will not require so much as those that have been so treated. *Disa grandiflora* and the hybrid *D. Veitchi* are very thirsty subjects when growing freely, and may be kept moist at the roots as well as freely sprinkled overhead as long as the weather keeps open. Plants of *Cattleya citrina*, too, that have been resting in the cool house will by now be well on the move, and may be kept moist. They will be all the better for a slightly higher temperature, but not so high or so dry as that of the usual *Cattleya* house is at this season. If the night temperature of the *Odontoglossum* house is kept at 50° this *Cattleya* is better here than anywhere, but this figure is the lowest that should be reached, or the plants may be checked, and the flowers as soon as they appear will turn yellow and drop off. This will also result from too high and too dry conditions.

Though the *Cattleya* house is still gay with the flowers of the old *C. labiata* and one or two of the earlier *C. Percivaliana* and *C. Trianae*, there is not much to be done. A few plants of the former have just been potted, as root activity seemed imminent, and sundry other small attentions to compost have been given. Still, the slackest time of the year in this section is here, and may be taken advantage of by giving a thorough cleansing, not only of the plants themselves, but of the house and stages. About the bases of the older leaves and flower-spikes and under the

external sheaths of the pseudo-bulbs are favourite haunts of the soft white scale, and a clearance of this is an advantage just now. Stakes and ties may also be renewed, and where the growth of such as *C. Lawrenceana* and others seems to be straggling, let the young bulbs be tied into place a little. Large plants coming into bloom may also be tied into form a little, as after the flowers are open and have lost the power of twisting to face the light they are more difficult to handle. Not much damping is necessary in this house, and the pipes must especially be avoided, as the steamy vapour which rises therefrom is injurious both to the plants and flowers. Maintain a buoyant atmosphere by free ventilation whenever possible; always leave a little air on at night, excepting during the coldest weather, but avoid dry, chilling draughts.

In the warmer division *Pendrobium Phalenopsis* is the principal attraction, and very lovely it is with its arching racemes of flowers varying in colour from white to the deepest crimson-purple on the better varieties. Rest the plants, if possible, after the flowers are past, as there is nothing gained by rushing them into growth at this dull season. Later flowering specimens will be even more difficult to keep dormant, but they are better so if possible. Most of the better-known deciduous and evergreen kinds are now dormant as far as growth is concerned, but the flowering nodes on the former are beginning to push. Except where required very early, they are better in a cool, light and airy house a little longer. *Calanthes* must be kept quite dry at the root when the flowers are fully expanded, and all the distichous-leaved section will need the utmost care in watering. Avoid excitement in every way, in fact, and where a few plants are evidently bent on growing, take them, if possible, to another house, such as a plant stove, where they can in a gentle way be kept moving all the winter and be ready to return to their proper quarters when the season is sufficiently advanced.

Oncidium hæmatochilum.—This pretty species is far from common, and it is a pity it is not more plentiful. It belongs to the bulbous section of the genus and has fine dark green leaves, spotted with dark brown on the upper side, from the bases of which spring the tall flower-spikes. About a couple of dozen flowers occur on each spike when the plants are strong, their sepals and petals being a greenish shining yellow, overlaid with spots of reddish brown in some cases, in others a bright, yet deep cinnamon. The lip, too, varies in colour from rose to deep crimson. The plant is a native of New Grenada, presumably at a low elevation, as under cultivation it does best with more heat than most plants from that neighbourhood. In a cool house the leaves will be subject to a soft spotting, which is very unsightly and distressing to the plants. The best compost consists of three parts of Sphagnum Moss to one of peat fibre, with an ample addition of large crocks and charcoal, and the plants should not be potted oftener than is absolutely necessary, as they greatly dislike being pulled about at the roots. Water freely while growth is active, but during winter give very little, the large, thick leaves containing almost as much nutriment as a pseudo-bulb, and this keeps the plant going. It is not right to go to extremes, of course, but it needs far less water than most while at rest.

Oncidium reflexum.—This species is but little grown, yet it is a useful and pretty kind that may with advantage be included in any collection. It is quite distinct from any of the other long-branching, spiked *Oncidiums*, having egg-shaped bulbs and fine deep green foliage. From these spring the tall spotted scapes, rising to a height of about a yard. The blossoms are individually 1½ inches across, pale yellow, with reddish brown markings on the sepals and petals, the lip much brighter and also tinted with red about the basal part. The plant is a native of Mexico, and thrives well at the cool end of th

Cattleya house, in such a position that the air plays freely about the foliage. If grown in much heat and moisture without plenty of air, it keeps on growing and seldom flowers. The pseudo-bulbs finish up early in summer, and a short time only elapses before the spikes appear, but they are a long time in coming to perfection. During this time the plants must not be allowed to get very dry, and as soon as growth again starts they require an abundant supply of water. They may be grown in medium-sized pots, these being well drained and filled with a compost consisting of good rough fibrous peat and Sphagnum in equal parts, allowing plenty of rough chareal and potsherds to keep this open. Like all in this section, it is apt to be attacked by green-fly when the spikes are pushing up, and it will be necessary to pass a damp sponge over the spikes about twice a week until the insects are all destroyed.

CATTELEYA DOLOSA.

The blossoms of this pretty species are produced during late autumn and winter, and it is a useful and showy kind that might with advantage be much more freely grown. In habit it is small, the pseudo-bulbs seldom more than a few inches high, but the flowers are of good size and very pleasing in their soft rosy mauve shade. The culture of *C. dolosa* is not perhaps quite so easy as that of the larger growing labiate forms, but with care it will thrive in any ordinary Cattleya house. In former days it was almost universally grown on blocks, often of teak, without a particle of Moss or anything else for the roots to enter. The growth naturally was very small and weak, so the species obtained a name for being even more difficult to grow than it really is. These blocks of smooth wood are all very well if the atmosphere of the house is always kept moist and one could be sure that the roots would not suffer from want of moisture, but that is just where they fall off. Blocks of Fern-stem are much better for *C. dolosa*, but if these cannot be obtained, baskets and pans may be used. In these the drainage may come well up, within an inch of the rim for medium-sized and rather more for large plants, the compost being the usual one of peat and Sphagnum mixed with plenty of chareal and crocks. In this the roots grow freely enough, but require care in watering, especially when just forming and again after the growth is made up. In the middle of summer, when the plants are growing freely and evaporation is rapid, they take a fair supply, but it is easy to be too liberal with the moisture. Growth commences, as a rule, in early spring, and this is as good a time as any for re-basketing where this is necessary. In all cases the plants should be disturbed as little as possible, a cheek being easily given by rough handling, from which the plants will not readily recover. As soon as the plants are beginning to root freely again, the moisture must be increased, for the top growth will be active and continued right on until the flowers open. It is unwise to leave the flowers on the plants until they fade if the latter are at all weak or only partly established. After flowering, keep the roots well on the dry side, but avoid shrivelling, and take great care that no insects of any kind are allowed to harbour about the rhizomes or pseudo-bulbs.

C. dolosa is sometimes classed as a variety of *C. Walkeriana*, but although the flowers are somewhat alike, the fact of its blooming on the pseudo-bulbs and not from a separate growth seems to point to a different species. It is a native of Minas Geraes, and was introduced in 1872.

Dendrobium nobile cœrulescens.—Where flowers are wanted very early in the season this dwarf form is one of the best varieties to grow. Whether this arises from the fact of the stems being shorter and therefore finishing earlier, or whether it flowers naturally earlier, I cannot say, but certainly it is more easy to bring into bloom in the middle of winter than the long-stemmed varieties, and not so prone to growing at the

nodes instead of flowering. It is well to keep the same plants every year for this purpose, as they then get into the habit of finishing the stems early and have plenty of time to ripen thoroughly before going into heat. If the stems are not ripe, it is better to keep them back a little, or the flowers will probably be of poor colour or abortive and badly shaped. *D. n. cœrulescens* bears very deeply-tinted blossoms, neither so large nor quite so wide in the segments as those of other kinds. It was one of the plants sent home to Chatsworth by Mr. Gibson when collecting for the Duke of Devonshire about 1837.—H.

A SUCCESSFUL HYBRIDISER.

LUTHER BURBANK was born on March 7, 1849, at Lancaster, Mass., and was first employed in the Ames plough works at Worcester, Mass., of which his uncle was superintendent for half a century. But service in a noisy factory was not compatible with his love of Nature, and in 1870 he purchased a small tract of land at Lunenburg, Mass. Here began Mr. Burbank's career as a horticulturist, and in 1873 he raised the Burbank Potato. Finding

Luther Burbank.

the climate of New England unsuited to the requirements of experimental work, he removed in 1875 to Santa Rosa, Cal., where he now has extensive grounds and a large collection of Lilies and many other plants, shrubs and trees.

Mr. Burbank has many times duplicated his first success with the Potato. He grew more than a million seedlings to establish a new race of Gladiolus, and the Cannas, Iris, Calla and the Rose have also responded to the care of this adept hybridiser. Raspberries, Blackberries, Walnuts, Quinces, Prunes and many other fruits have been developed to man's greater good at his garden. Besides his greenhouses and ten acres of home grounds on Petaluma Avenue, Santa Rosa, he has a farm a few miles distant, at Sebastopol, where eighteen acres are given over to seedlings and thirty acres devoted to farm experiments. So fully is Mr. Burbank's time occupied by his studies, tests and correspondence, that he refuses to admit the public to his gardens except in the month of June, which is reception period for intending purchasers. Then those who anticipate a view of uniform rows of beautiful plants or healthy shrubs and vegetables are sadly dis-

appointed, for they find, instead, chaos, a veritable horticultural workshop.

A story which Mr. Burbank delights in telling is that of a member of one of the largest seed firms in the country who had travelled over 3000 miles to see the workings of this hive where man and Nature join in industry. On the way from the station the visitor overtook an old gentleman who had worked many years for Mr. Burbank, and inquired of him if he knew Burbank. "Of course I do," was the reply. "He used to have a big nursery, but sold it out, and now he raises acres and acres of stuff, and every summer has 'em all dug up and burned. I wouldn't give a hundred and fifty dollars for the whole kerboodle." The gentleman from the Atlantic stored away this gratuitous advice, but before the day had passed he selected from Mr. Burbank's stock a half-dozen plants for which he paid 6000 dollars.—*American Florist*.

BOOKS.

INJURIOUS INSECTS.*

A VERY useful "Handbook of Insects Injurious to Orchard and Bush Fruits" has quite recently been published by Miss Ormerod. It really consists of the articles on these insects from her well-known "Manual of Injurious Insects," written up-to-date. In addition to the insects attacking orchard and bush fruits, those injuring Strawberries are also dealt with, as well as two kinds of eelworms and three mites; in all some sixty-three pests are described, and in the majority of cases figured. This book will no doubt prove a very useful one to all fruit growers, as it is of very handy size, containing 286 pages. It might have been reduced by many pages and the information required by practical men more easily obtained from it if the notes by correspondents were not given verbatim, and the whole more tersely worded and condensed. The book is dedicated to the memory of the authoress's sister, who very materially assisted her in her entomological work. In speaking of the American blight, Miss Ormerod says, "The pupæ (that is, the aphides before grown to maturity) are," &c. This is misleading, as the larvæ are also the aphides before grown to maturity. On page 21 there is a mistake that should be corrected in another edition. Wishing to allude to the late Professor Westwood (life president of the Entomological Society of London), the authoress mentions Professor Westwood, life president of the English Entomological Society, whatever that society may be. Two insects are described and figured which can hardly be considered as pests, the lappet moth (*Gastropacha quercifolia*) and the large tortoiseshell butterfly (*Vanessa polyphloros*). As they so seldom are the cause of any appreciable injury to fruit trees, it seems hardly worth while to have mentioned them, and, indeed, the authoress almost admits as much. The large tortoiseshell butterfly is one of our handsomest English insects, and it would indeed be a pity if it were destroyed unnecessarily. In the article on the garden chafer (*Phyllopertha horticola*), the great resemblance of its grubs to those of the common cockchafer (*Melolontha vulgaris*) before the latter attain their full size is commented on, and in order to enable persons to discern the difference between them, a Latin description of both grubs has been translated by an Oxford M.A. The exact meaning of the Latin I have no doubt has been most correctly given, but the language is so technical, that no one but an entomological expert could understand it. It is a pity that a more intelligible description to the "man in the street," or rather in the orchard, was not given. In the notes on the Currant mite (*Phytoptus ribis*) it is mentioned that it is very

* "Handbook of Insects Injurious to Orchard and Bush Fruits, with Means of Prevention and Remedy." By Miss Ormerod. Simpkin, Marshall and Co.

important to observe the number of the legs in order to prevent confusion in identification with other kinds of mites which may very likely be found on Currant bushes. This is very absurd, as the Currant mite belongs to the Phytotidae, a family of mites the members of which cannot be mistaken for those of another family on account of their very long, narrow bodies, which are some six times longer than they are wide, while most of the other mites are more or less rounded or oval. At any rate, the Currant gall mite could not be mistaken for any other mite of another family, so that fruit growers if they find their Currant bushes attacked by a mite, need not go to the trouble of putting the pest under a powerful microscope, as it would be necessary to do if they had to count its legs, for a really strong pocket lens will reveal its identity. The work concludes with a useful alphabetical list of fruit crops and the insects that infest them.

G. S. S.

FLOWER GARDEN.

ZAUSCHNERIA CALIFORNICA.

ON reading some notes in THE GARDEN on this, it does not appear to be generally known that there are several forms or varieties. I have grown at least three totally distinct from each other. First I will mention a variety I have grown and seen in gardens under the name of splendens, a straggling, weedy-growing form with coarse downy foliage, which in wet weather is liable to disease and quick decay. The flowers, although brilliant in colour, are so sparsely produced as to render it of little value as a garden plant, and altogether it is a worthless variety in comparison to two other varieties I will mention, one of which is so distinct as to suggest its being a true species. The one to which I refer is a very early-blooming form, invariably coming into bloom here (Cambridge) by the third week in July and continuing a beautiful mass of bloom until destroyed by late autumn frosts. The foliage and flowers of this variety are much deeper in colour than in other forms; it is of fine robust, yet compact habit of growth, and one wonders why such a fine, hardy and easily grown plant has never become popular for massing on a large scale in public and private gardens. In effect it is far superior to such things as Cupheas and other half-hardy plants generally used for such purposes. Given a sunny position and rather poor, well-drained soil, I believe this variety would succeed in any part of the United Kingdom. A few years ago a small number of plants, placed by mistake in a half-shady position, was allowed to remain. These quickly grew into a large mass and have never failed to be a sheet of blossom for eight or ten weeks each year, although coming into bloom a fortnight later than those planted in full sun. I think there is confusion in names, and this variety may be the true splendens, or it may be a Mexican form which I have noticed in continental lists under the name of mexicana, as the description of the latter corresponds very closely with that of the variety I have described. Whatever its proper name, source, or origin, it is undoubtedly a first-class and reliable plant, and if I were confined to growing a couple of dozen of the best and most reliable perennials this certainly would be included.

The third and last variety to be noticed is a much smaller plant in all its parts than the two already referred to, the foliage much more rounded, the habit of the plant more dense and compact, and the flowers much smaller, but of the most intense vermilion colour imaginable. I believe there are good and indifferent forms

of this variety—a thing easily accounted for where any plant is quickly raised from seed. This particular variety appears to require much greater heat to see it in its best condition than the other good variety referred to, and, treated as a hardy border plant, without any coddling, I have never known it bloom before the second week in August—nearly a month later than the other variety. The best position for this variety is probably the driest and sunniest part of a rockery, but in hot, dry seasons here it forms beautiful masses of bloom grown on a sunny border. A large mass of a good form of this seen in its best condition is a sight not easily forgotten. It is the most intensely brilliant-coloured flower I know. I have never seen it in finer condition than on a sunny border in a naturally poor, dry, warm soil, made more so by some large drains running directly underneath the plants. Wherever *Plumbago Larpentæ* thrives and blooms freely this variety of *Zauschneria* would be a success. J. BURRELL.

—Possibly my experience may give a hint as to the requirements of this plant. I cultivated it in Bucks from 1848 to 1858 in a south border of stiff clay, baked in summer into cracks 2 inches wide, and drained of its nourishment by shrubs and creepers against the house. Here it was very dwarf and flowered in profusion every year. In Kent from 1875 to 1885 it flowered equally well in similar (but poorer) soil. Here in Warwickshire on rich red sandy soil it grows freely, but nothing will induce it to flower. I am now trying the gravel walk.—JUNIA.

—My garden is in the south-east corner of England, has a great deal of sunshine, and the soil is of a light character. The warmer and brighter climate is, I believe, most congenial to this, but even with me it is only in dry seasons that it flowers profusely. It grows like a weed on my rockery, and I have continually to take out quantities of it. In a dry season like the past it has done uncommonly well, and the plant has been covered with its bright Fuchsia-like blossoms. I therefore conclude it is not the method of cultivation that is at fault, but the weather.—DELTA.

—I notice that the beautiful late summer and autumn-flowering plant *Zauschneria californica* is accredited with shyness of blooming in the north and elsewhere. Having tried this plant in various places and in different soils, I find a great deal depends on the variety one possesses. The better and earlier flowering sort, with leaves more lanceolate and tinged with red, has been found both in heavy soil in Sussex and Hertfordshire and in the light soil of a hot, sandy garden to be very free flowering, always arresting attention from August onwards. Of the later flowering kind, sold as *Z. c. splendens*, the growth is more vigorous, leaves very hirsute and of a pale green. It is altogether a more compact grower. The colour of the flowers is the same brilliant vermilion, but they are shorter in the tube than in the earlier variety. This was very beautiful this season in October here.—MAURICE PRICHARD, *Christchurch*.

—Had Mr. Arnott been able to see this hardy plant as I saw it at St. James's, West Malvern, in September last, he would hardly have penned the pronounced deprecatory note concerning it which appears at p. 467. At St. James's it grows in great clumps on the sharp slopes of that remarkable and beautiful garden almost luxuriantly, and was when I saw it a perfect mass of bloom. The soil is of a semi-volcanic character, intensely hard stone, pulverised by weather and years, the position the hillside looking west. I well remember the introduction of this plant in 1850 into the garden where I then served, and that it seemed to do well as an ordinary rock plant. The chief objection to its use was that its roots were too rambling. So far as my experience of it has gone it has always done better on elevated positions

than on the flat. That it is when in full bloom, as I saw it so recently at Malvern, a very beautiful thing there can be no doubt. Possibly were Mr. Arnott to select a sunny site and an elevated one, and intermix with the soil some well crushed lime-stone, he might obtain better results. Still, Damfrics may be too far north to enable it to secure that liberal sunshine and warmth it evidently needs. *Plumbago Larpentæ*, introduced at the same time, has perhaps never had its requirements fully met in this country. We too often have plants introduced with too little knowledge of their native surroundings.—A. D.

—Seeing a letter in THE GARDEN of Dec 10 which speaks in a desponding way of two plants which are favourites of mine—*Zauschneria californica* and *Plumbago Larpentæ*—it may be of interest to your readers to give them my experience. For years I grew the *Zauschneria californica* on the tops of walls and rock gardens in the sun and in the shade, in damp places and in dry, and it never died. I moved it in the autumn, and in the spring early in the year it looked flourishing enough, but in the autumn the same disappointment year after year—it never flowered. At last I happened to visit Mr. Thompson's most interesting little garden at Ipswich, and I found it flourishing and in full bloom, and exactly like its picture published in the old book of the fifties. He pronounced the magic word for its cultivation—a dry, sunny situation and very good feeding. I came home, planted mine in the corner of a vine border slightly raised, dry, and sunny in the richest soil I could make, and the result was quite satisfactory, and when the buds formed it was copiously watered once or twice, as the season was very dry. The plant was lovely, and the flowers look well in water. I saw it in bloom last summer in a friend's garden, and I knew he too had re-made his borders. *Plumbago Larpentæ* flowers very well here in poor soil, and its leaves as they turn red are as beautiful as the gentian-blue flowers. All I ever do to the plants here is to cut pieces out with a spade in the autumn, fill in with fresh soil, and water copiously as the plant is coming into flower in September. I can honestly say no two autumn-flowering, low-growing plants I know are better worth growing than these.—M. T. E., *Woodlands, Cobham*.

—This plant, which Mr. Arnott in his note (p. 467) alludes to as being a decided disappointment in the majority of gardens, is certainly a capricious subject, but may often be found flowering freely—at least in the south of England—under circumstances apparently the reverse of favourable. Probably the most suitable soil is a sandy loam, and the most desirable position a fairly elevated one in the rock garden; but I have seen it flowering profusely in a flat bed of heavy, retentive loam inclining to clay. Where it blooms freely it is one of the most effective late summer and autumnal herbaceous plants, the vivid vermilion of its blossoms at once arresting attention. It grows like a weed in most gardens in the south-west and generally carries some of its flowers into November. It is very probable, as Mr. Arnott suggests, that the cooler climate of the more northern portions of our islands acts as a deterrent to its flowering, but I was sorry to notice in the concluding paragraph a warning to intending growers not to attempt its culture, for the planting of a single specimen would entail but little trouble or loss of space if it remained flowerless; whereas if the experiment happened to prove successful, the conductor of the trial would be amply repaid for his venture. In the same note *Plumbago Larpentæ* is spoken disparagingly of. Here, in South Devon, it grows rampantly, rooting through rockwork and gravel paths and producing quantities of its soft blue flowers. This plant, again, though usually considered partial to a porous compost, grows vigorously and flowers as abundantly in very heavy soil close to water as on high and well-drained positions in the rock garden. Doubtless the warmer temperature of the south-west is responsible for the success attending the culture of this *Plumbago*

and the Californian Fuchsia under the dissimilar conditions mentioned.—S. W. F., *South Devon*.

WATER LILIES AT OAKWOOD, WISLEY.

THE photograph of the Marliac Water Lilies growing in a pond at Oakwood, Wisley, was taken by my son, Mr. Scott Wilson. Visitors to the garden have greatly admired the plants; they are so beautiful and give so little trouble, that I think they ought to be very generally grown. They have an additional merit, that when a pond is made muddy by carp or other fish, they cover the surface. The pond is in full sun in a warm situation, and this suits them, as is shown by the size of the leaves. The older forms are no longer expensive. *N. Marliacea Chromatella*, the yellow form, contrasts well with the pink-flowered kinds.

GEORGE F. WILSON.

Tropæolum Lobbianum.—"J. C. B." in his note (p. 467) draws well-merited attention to the decorative qualities of this brilliant creeper. Owing to the mildness of last winter many old plants survived, and have this year clambered 20 feet or more up the walls of houses and cliffs. One cottage was scarlet to its chimney with the countless vivid blossoms, and on a perpendicular rock-face, sheltered from all winds but the south-west, even at this date (December 15) a few blossoms may still be seen shining aloft among the huge seed-vessels of *Physianthus albens* and the smoother pods and polished foliage of *Stauntonia latifolia*. A charming effect is obtained by the association of the bright blossoms of the *Tropæolum* with the white flower-clusters of *Solanum jasminoides*, the two colours forming an attractive contrast.—W. S. F., *South Devon*.

Anomatheca eruenta.—This pretty little South African bulbous plant, which has been several times referred to in THE GARDEN of late, is a great favourite of mine, and, apart from the fact that it forms a very pleasing feature on a warm sandy border, it is also very useful for the greenhouse. The bulbs of this *Anomatheca* are something like those of a *Freesia*, but smaller, and in order to obtain neat little specimens, from eight to ten bulbs should be put into a pot 5 inches in diameter, while for larger masses pans are preferable, as the *Anomatheca* is a shallow-rooting subject, hence no great depth of soil is required. It possesses one prominent feature that renders it remarkable among bulbous plants, and that is the seeds which ripen one year will produce flowering plants the next. With me self-sown seedlings crop up here and there, and being allowed to remain undisturbed, their little bright flowers are towards the end of the summer to be met with under various conditions. This *Anomatheca* produces bright green sword-shaped leaves about 6 inches long, while the flower-scape will reach a height of nearly a foot. The blossoms, which are borne in considerable numbers, are each nearly an inch across and of a bright carmine-red colour, while the lower segments are blotched with velvety crim-son.—H. P.

Heather protection.—Very noticeable is the great quantity of cut Heather employed for protecting beds of bulbs or other choice things at Long Ditton, and its free use in this way merits attention by gardeners because it is cheap, enduring, and does not beat down and become saturated as litter or Fern is apt to do. Whilst lying light and enabling air to penetrate to the soil, yet does the Heather largely exclude severe frost and ward off the beating rains which so

harden and close the surface of recently-worked soil. Gardeners may find similar material of great service in gardens for many purposes, and secured against strong winds would not be offensive.—A. D.

CARNATION NOTES.

SOME varieties are longer than usual in making roots this season. It may be the soil I used when layering was a bit close and heavy for the more tender kinds. These backward ones, however, have been taken from the old stocks about a fortnight and potted singly into a porous soil composed of loam, leaf-mould and a good proportion of sand. They are in a light, airy greenhouse, where a little fire-heat is turned on at night. Warmth has not been necessary during the day, as the weather has been unusually mild for the time of the year. I have also lightly sprinkled the plants with water in the mornings of sunny days. It is surprising how quickly they have responded to this treatment. The leaves have pricked up

house or frame through ventilating in the opposite direction to such winds. It is well to use some slight protection if the weather becomes unduly cold and frosty. Close, damp conditions are favourable to spot in the leaf, and this readily spreads. It is really a disease, but one that is checked by dry, sweet surroundings.

The principal cultural item of the December and January months is to guard against this and other pests likely to seriously check, if not altogether ruin, our chances of a satisfactory flowering time. Few cultivators, I should imagine, are more particular in the matter of timely attention to diseases of Carnations than is Mr. F. A. Wellesley, Woking. His thousands of young plants are at the present time the picture of health and cleanliness. A spotted leaf is quickly removed. The more troublesome red rust is as regularly looked for, and if the slightest sign is noted, off comes the affected part, which is burned. By this means and by isolation in serious cases his collection is unusually clean.

The rust is really often on Carnations whilst

A group of Mons. Marliac's Water Lilies in Mr. Wilson's garden at Wisley. From a photograph by Mr. Scott Wilson.

and new roots have in many instances reached the sides of the pots.

The stronger and by far the largest portion of my Carnations is well established in small pots. These are in cool houses, a position for the winter better perhaps than frames, preferred if for only one reason—one can more readily attend to the wants of the plants. Frames are valuable for the winter quarters, inasmuch as they are cool, but the damping is not so well overcome as when light greenhouse stages are used. On these lattice-work bottoms air passes as freely about the pots as among the leaves; this is a great consideration. If frames are used, one may imitate such staging by placing boards on inverted flower-pots, thereby raising the plants close to the glass. This is an advantage in keeping a dry as well as a cool atmosphere. Air at all times is a necessity, the plant being quite hardy. What does harm to Carnations is cold, cutting winds. These conditions may be avoided by allowing air in green-

the cultivator is ignorant of its existence, the early stages being noted as tiny specks. At this time of the year it has the appearance of mere brown dusty spots, but by and by, if these are all allowed to develop, one will have no difficulty in seeing its larger form, which comes in wart-like lumps that burst and spread with great rapidity. The maggot is one easily dealt with if we are prompt. That is to say, its whereabouts are known by the white marks left behind in its way between the tissues of the leaves to the centre or pith of the plant's stem. This is the goal of the maggot or grub, and of course when that spot is reached the plant is useless for blossoming well the following year. I find a stout needle a capital instrument to catch this enemy. The work is not so easy in dealing with outside plants as with those under glass, but it must be done.

Watering requires some care during winter. The soil may not be allowed to become dusty, but still it is best kept on the side of dry-

ness rather than in a soddened state. The latter soon leads to sourness and a loss of roots. Let watering be done during the earlier part of the day, so that superfluous moisture can dry before night. I use a small can, so that individual plants are easily picked out and their wants supplied. Care, too, is taken not to wet the foliage.

It is advisable to get the potting soil under cover now, as the plants intended for pot culture will be ready for a shift by the end of February and early March. This matter is too important to be left until required. If kept outside, the chances are that it will be in too soddened a state for use. Some growers even mix the compost months beforehand, but this is not so necessary, to my thinking. Loam is the chief part; this should be as full of fibre as possible. Thoroughly rotted manure, with a supply of leaf-mould in the same condition for the more weakly sorts, and coarse sand should also be at hand when required. Charcoal, again, is of great assistance in keeping the soil open and sweet.

The foregoing remarks apply more especially to pot culture; but in dealing with soils in the greater number of localities the better plan is to winter the Carnations in pots even if intended for an outdoor display; the plants can be managed easier in regard to pests and diseases, and one feels they are safe. On the sandy soil of this neighbourhood they usually winter well in the open ground. A rule, however, is to layer early and plant out before November, and in an ordinary season we look forward to good results. But in wet soils the losses of plants are generally too heavy, and it is wiser, I think, to take the extra trouble in potting and protecting with glass during the winter months. H. S.

Woking.

NOTES FROM NESTON, CHESHIRE.

I CAN add some items of interest on three points touched on in your last issue. From a letter just received from Mr. Edward Whittall, I find that it was his nephew and not himself who was carried off by brigands. Mr. Whittall gives a harrowing account of the state of things at Smyrna. A prolonged drought has resulted in widespread famine, and the poverty-stricken villagers are caught between the heavy hand of the tax-gatherer and the frightful prices now asked for food stuffs. Robbery and crime of all kinds have naturally become rampant. Mr. Whittall sends seeds of a new *Glaucium* with flowers of so brilliant a crimson, that they were conspicuous on a hillside half a mile off. The blue *Primula* mentioned in Sir J. D. Hooker's "Himalayan Journals" and referred to by "J. J. R." is *P. sapphirina*. I most heartily agree with him that it is most desirable to get it into cultivation, if only for the more effectual confusion of the washed-out or livid puce which are passing in the trade as the blue *Primrose*. Sir George King informs me that *P. sapphirina* is one of the most perfect gems in all the Himalayan flora. Some years ago he sent seeds of it home, but no trace or record of it is now to be found at Kew. Unfortunately, it is not among the exciting alpine plants of which Mr. Hobson has been sending seeds from the Sikkim-Thibet frontier. Last May, however, I heard from Dr. Prain, who has succeeded Sir George King at Calcutta, that the Sikkim collections, which have been almost abandoned for some years owing to causes connected with the native Lepcha collectors, are to be resumed and vigorously pushed; so there is good hope that we may shortly have the real blue *Primrose*.

In connection with Mr. Bean's most interesting article on the shrubby *Hypericums*, it is worth noting that there is a herbaceous species yet to come of a highly exciting character. This is *H. leve var. rubrum*. It is described in Dr. Post's

"Flora of Syria and Palestine" as growing on calcareous hills from Ain Tab northwards and eastwards, and having petals more or less deep red. I hope to have seed of it next year. What a pity it is that those of us who care for hardy plants do not unite to send a collector yearly to some of the many rich hunting grounds still untouched. I find that a £5 note will work wonders. A few of us united could probably send a collector, trained by Mr. Ford, of Hong Kong, to the wonderful alpine riches of Yunnan or Western China. Why does the Royal Horticultural Society do nothing? ARTHUR K. BULLEY.

Neston, Cheshire.

DESTROYERS.

DESTRUCTION OF WORMS IN LEEKS AND CATERPILLARS IN CABBAGES.

FOR some years past Leeks have in the course of the summer been attacked by worms, or rather a kind of diminutive caterpillar, which cuts the leaves to such an extent that the plant is rendered worthless. Sometimes even whole breadths are completely destroyed. After trying many ways of destroying this insect, I at last succeeded in getting a good result from using a solution of black soap. The mode of operation is as follows: Dissolve 2 ozs. of black soap in three pints of water and spray the plants with this solution, taking care to aim the syringe at the inside of the Leek, so that the liquid may descend into the heart of the plant. The grubs will be destroyed on the spot.

Although this dose of soap may appear a strong one to many, I affirm from numerous trials that this quantity is necessary to ensure success. If after several days living grubs are still to be found, it is well to repeat the operation. If, however, the first has been carefully performed and rain has not immediately followed, it will rarely require to be repeated. It ought to be undertaken only when the plants are dry and there is no water in the heart, as this water would lessen the force of the insecticide.

Soft soap dissolved is the best insecticide for caterpillars, but the dose of soap should be stronger for big caterpillars than for small. For caterpillars on Cabbages nearly 75 grammes of soap will be required to the litre of water; for other larger caterpillars the dose should be raised to 100 grammes of soap to the litre, but do not exceed this or it may injure the plants. To get a good spray with strong solutions of soap it is preferable to serve these rather warm. A good result also is obtained by adding petroleum to the soap solution, in which case the dose of soap may be lessened by one half—for example, 25 grammes of soap and 25 grammes of petroleum to the litre of water for small species of caterpillars, and 50 grammes of soap and 50 grammes of petroleum for the large kinds.—G. D. HUET, in *Revue Horticole*.

THE PEAR MIDGE.

I WAS particularly interested in reading the article on this subject in last week's issue of THE GARDEN, as I have been a considerable loser by its depredations in the last few years. It is difficult to say when the insects first put in an appearance in these gardens, but the attack was not sufficiently serious to attract attention until five or six years ago. The worst attack occurred three years since, when a great number of the most prominent fruits was injured on bush trees, and to a less extent on wall trees. I destroyed great numbers by hand-picking, but being but imperfectly acquainted with the life-history of the insect, knew not what other measures to take to circumvent it. The following year the attack was less virulent, and since then it has gradually become less, but still I have not got rid of the pest altogether, as was only too plainly to be seen by the swollen or gouty appearance of some of the fruits last sum-

mer. Since reading in the article in question that the larva of the Pear midge buries itself not deeper in the ground than 1 inch, and that the caustic solution caused by the dissolving of kaimit is supposed to kill it, it has occurred to me that I have, though unknowingly, been reducing the numbers by the simple fact of spraying the trees with alkali wash each year. A good deal of the latter falls to the ground as the trees are being sprayed, more so under wall trees than out in the open, and it is easy to imagine that as it becomes absorbed and washed down into the soil by rain, a great many of the larvæ are then destroyed. Another thing which perhaps may account for the difference in the nature of the attack between wall and bush trees in former years is that the alleys under the walls were left undisturbed until after the spraying was done, while the ground under the bush trees was pointed over a few inches deep as soon as pruning was completed. In the latter case the spraying led to the newly dug soil being trodden so hard about the trees that I had the pointing postponed in consequence last year, when the attack certainly was nothing nearly so serious as it had been previously. The fact of merely pointing the ground over no doubt placed many of the larvæ just out of harm's way and no more, as deep digging cannot be resorted to without great destruction of surface roots following. I may, of course, be wrong in my surmising, but I intend paying particular attention to the matter this winter, and shall have the surface thoroughly wetted under several trees, and sufficiently so that the soil is moistened quite an inch in depth, and then await results. The varieties most subject to attack with me are Jargenelle, Beurré d'Amanlis, Doyenné d'Été, Marie Louise, and Doyenné du Comice. There are, however, several other sorts, but those named have been the worst sufferers in this respect. A. WARD.

THE MARKET GARDEN.

MARKETING APPLES.

WITH the exception of the market men, who bestow the necessary amount of forethought and labour on the subject, the above is one of the things in which much has yet to be learnt by farmers and cottagers. There has certainly been an improvement of late, but such practices as shaking Apples from the trees, putting them pell-mell into the baskets, or packing a few layers of fine fruits on the top with inferior ones below have not, it is feared, yet died out, although the fear of exposure in the market has done much towards putting a stop to it. When the fruit is properly gathered and graded by making two samples of them, putting the best in one package and the seconds or inferior ones in another, then farm and cottage growers will obtain a much higher price for their produce than they do now. Packing, too, must be carefully done, so that the fruit will travel long distances when required without its being repacked again. Prizes are offered each year in open competition for the best-packed basket or box of Apples at the annual fruit show held at Hereford, which gives everybody a good practical object-lesson as to the manner in which fruit—particularly Apples—should be packed. Mr. Meats, the official auctioneer, also offered prizes for the same object last November, the conditions being that the fruit was to be packed in "corporation" hampers only. By these means, and by keeping the matter constantly before growers and the general public, it is hoped that the new methods will speedily displace the old, and that careless gathering, faulty grading and packing will soon become things of the past.

A great deal of the fruit is disposed of in the local market, where it is bought up by dealers

who attend for that purpose, and is then promptly despatched to various large towns. On the other hand, there are those who prefer to send their produce direct to such centres as Manchester, Cardiff, Liverpool, and Birmingham, where it is sold on commission. At any rate those who produce good quality fruit experience no difficulty whatever in disposing of it. Such has been the demand for Apples this year, that immense quantities of fruit, such as is usually converted into cider, have also been bought up, which have, it is said, found their way to the jam factories. Various kinds of packages are used for despatching the fruit in. For the local market (Hereford) the fruit is packed in the hampers supplied by the corporation, each of which holds about 56 lbs. of fruit. Others use pots such as are employed in the Evesham district, and these find favour in the northern part of the county. Others, again, pack in half-bushel and bushel sieves, and a great number avail themselves of barrels which hold from $\frac{1}{2}$ cwt. to 1 cwt. each. If the packing is properly done, the latter are first-rate receptacles for despatching fruit in to long distances, as they are easily handled and the contents are not so easily bruised as when packed in baskets.

Prices, of course, vary considerably. During the past season something over £1 per cwt. has been realised for choice samples, while for good quality fruit the prices have ranged from 10s. to 18s. per cwt. Medium quality fruit made from 7s. up to 10s., while inferior samples fetched from 3s. to 5s. per cwt. Many tons have been disposed of during the past autumn at the latter figures, quite a brisk trade having been done in this class of fruit. A. W.

STOVE AND GREENHOUSE.

LAPAGERIAS.

PERFECTLY cultivated plants of either of the varieties of *Lapageria* are not particularly common, and it is a curious fact that in many cases where apparently little trouble is taken with them they do remarkably well, while in others the cultivator may try his utmost and only be partially successful. In the old-fashioned dark houses—still, unfortunately, in vogue in some places—*Lapagerias* may frequently be seen doing well, and owing partly to this the plants have been considered by some to need a very dense shade. As a matter of fact, it is almost impossible to give them too much light, especially in autumn, but the light must be accompanied by a proper supply of air night and day. In Gloucestershire a few years ago I saw one of the finest *Lapagerias* I had ever seen, and this was growing over the roof of a large conservatory the glass of which was entirely unshaded. Cool house Palms, large Camellias and other plants were grown in the house, and the immense *Lapageria* formed a welcome shade over these, though itself exposed to the full sun. Every year large sucker-like shoots pushed up from the base, almost as thick as a man's finger, grew at a great rate and covered the large expanse of roof. The house was always freely ventilated and damped, and there is no doubt that the moist atmosphere without an approach to closeness tended to make this plant a success. Anyone who is trying to grow either the white or red kind in small cooped-up structures should give his plants more light and air.

Lapagerias abhor being disturbed at the roots, and more than once I have turned out large old plants that had been shifted several

times and could see the ends of the roots dead after each shift. The sooner the cultivator makes up his mind where a plant is to be put and puts it there the better chance that plant has of growing to a large size and good old age, for although each new stem puts forth a fresh tier of roots on its own account, after the manner of herbaceous plants generally, a great check is given whenever the young points of the roots are in any way bruised or damaged. Again, the roots are curious in their likes and dislikes. I have traced them for several feet through the hungry red sand of the West Gloucester district where they seemed to positively revel, and have, on the other hand, found them blackened as if burnt when they have approached a lump of good turfy loam. This explains why many plants, after apparently getting well established, often sicken and refuse to grow. As long as they remain in the border prepared for their reception they are all right, but perhaps this border has been dug out where the natural soil is a stiff clay; the roots reach this and make no further progress. They often do the same thing if planted in a new pot or a painted tub or box. It is evident then that to grow a *Lapageria* properly one must have a suitable root-run that the plants will not grow out of for a few years. This is easily provided, and the next care will be to avoid over-moistening this somewhat large bulk of compost before the roots have had time to take hold of it. A deep root-run is not necessary—should be avoided in fact—but if a few roots can be coaxed to any constantly moist spot, such as often exists in greenhouses and conservatories, it is surprising how the plants appreciate it. A free-working loam without much lime in it, plenty of properly prepared leaf soil and peat, with enough sharp sand and nodules of charcoal to prevent the whole settling closely, is a compost suitable for *Lapagerias*. When well established in this, feed the plants liberally from above, and this will ensure a quick growth and at the same time prevent the roots descending to bad soil in search of food.

Regarding the choice of plants, I would always prefer nice healthy, young layered ones, or even seedlings to large specimens that have been reared in pots, by reason of the peculiarity of the roots noted above. Where for years the growths have been twined and trained round sticks or some similar support, they are almost sure to be covered with insects of one kind or other, but clean, young plants may be kept so by exercising ordinary care. Almost every known blight preys on these plants if allowed to. Green-fly attacks the tender young shoots, while scale and mealy bug are fond of the older leaves and stems. Perhaps the worst of all, however, is thrips, this being one of the most troublesome to destroy. When a plant gets really dirty, repeated fumigations are necessary, and these must be followed by cutting out the weakest and worst affected shoots and by diligently sponging with approved insecticides. If the syringe is freely plied about the plants morning and evening all through the growing season, it helps to keep them clean, and if clean water is used, it will not damage the flowers. H. R.

Andromeda floribunda in pots.—What a useful shrub this is! It is especially good for lifting in a medium-sized state and potting for decoration at the dull time of the year. Nice dwarf, well-furnished plants placed in 9-inch or 10 inch pots in any loamy and leafy compost come in most acceptable for the conservatory, and even though the flowers are not of the purest colour, sprays cut and arranged in glasses have a cheerful

look about them. As a border plant it succeeds very well in a light sandy loam, and if a little peat can be added, so much the better; failing the latter ingredient, leaf-mould is a good substitute.—B. S. N.

Coloured Selaginella.—As an edging to the fine group of *Chrysanthemums* which Mr. Norman Davis had arranged at the recent Aquarium show was a quantity of *Selaginella denticulata* beautifully coloured, and in the artificial light singularly beautiful. I found that it was hardly less charmingly coloured in the daylight. He said in request for an explanation as to this unusual coloration that the house in which it had been grown had been allowed to become both cold and dry, and the low temperature seemed to have been the chief cause of the fine colour.—A. D.

Terra-cotta Carnations.—It is rather singular that up to the present no really good reliable terra-cotta-coloured Tree Carnation has found its way into commerce. Such a variety is really what is needed, as it is a fashionable and much-appreciated colour. A few years ago a friend of mind living in Suffolk raised a vigorous, free-flowering terra-cotta variety, the flowers being of extra large size and very shapely. Blooms of it were sent to a London salesman, who declared that if the raiser could only secure a good stock of it, it would bring him a little fortune. Somehow or other he failed to do this, and I have an idea he lost all the stock.—C. N.

Pink Tree Carnations.—Opinions seem to differ much as to which is the best all-round pink winter flowering Carnation. A few years ago those who could not grow Miss Joliffe could find no substitute. Since then several others have been introduced, amongst them *Thérèse Franco* and *Reginald Godfrey*. The former, however, does not seem to deserve the praise accorded it at the first by some, and I learn that market growers are discarding it. *Reginald Godfrey* seems to be gaining favour, but it will not only have to produce good blooms, but plenty of them if it is to replace Miss Joliffe. *Mistral* is spoken well of as a good pink-coloured tree variety, but I have not proved it. What is wanted is a variety as free-flowering as Miss Joliffe.—N.

Pellionia decora.—This is a pretty little creeping plant suitable for hanging baskets in a moist stove. The stems are bright red and the leaves velvety green, striped and prettily mottled with a silvery white. The younger leaves are pale green with a red suffusion. It is like some of the better *Fittonias*, but smaller in all its parts, and under artificial light has a very beautiful appearance. It is a free grower when established, growing from a number of joints and forming a dense plant, well filled out in the middle, where *Panicums* and similar things are often bare. It strikes readily from cuttings in a light sandy soil, and should be grown in a rather poor, but light and open compost, keeping the roots moist all the year round.

Carnation Belle Rose.—What a pity it is that this grand Tree Carnation cannot be grown with more certainty. If only a remedy could be found for its dying off it would be the most profitable scarlet variety in cultivation. The colour is rather paler than in the well-known *Alegatiere*, but very delicate, and on well-grown plants the blooms come of large size. Unfortunately, one may grow a batch of large bushy plants and house them in perfect health only to see them go off wholesale during the winter. The grass withers without the least warning, and the plant is gone in a few days. A few growers seem to manage it well, and Mr. Taylor when at Longleat used to do it splendidly. He practised disbudbing, and the individual flowers were very large. In one garden in Kent a sufficient number of plants to fill a 50-foot house was grown, but as a rule nearly half the plants died off before the spring.—J. C.

Begonia President Carnot.—Could you inform me what is the best temperature to winter *Begonia President Carnot* in? I have been keep-

ing it in a moist temperature of from 60° to 70° and found it damp badly. I then placed it in a drier place in a temperature of 50° to 60°, and still find it damp.—A. P.

* * This *Begonia* will winter well in a temperature of from 60° to 70°, but it is necessary that a fairly dry atmosphere be maintained, otherwise the foliage will damp. A temperature of 50° to 60° is too low to keep the foliage in good condition throughout the winter. In some districts, especially where fogs prevail, and this applies particularly to the neighbourhood of London, many of this class of *Begonias* will lose nearly the whole of their leaves, but will break again freely with the return of spring. When the foliage shows a tendency to decay, it may sometimes be checked by removing the plants to the driest portion of the structure and refraining from wetting the foliage. Elevating the plants on pots will do something towards checking decay, and, of course, the watering must be carefully done, the soil being kept rather dry than otherwise. In the case of *Begonias* belonging to this section when the foliage once begins to decay it is by no means an easy matter to stop it during the depth of winter, but the above instructions if carried out will help to tide over the difficulty till the growing period comes round.—H. P.

CESTRUM ELEGANS.

This is, perhaps, better known as *Habrothamnus elegans*. Although not, strictly speaking, a climber, it is a fine plant for a conservatory wall, and requires some room to flower it well. I have seen it planted alternately with *Plumbago capensis*, the crimson and blue forming a good contrast, and by judiciously thinning the plants some bloom may be had nearly throughout the year. As a greenhouse plant it cannot be too highly recommended, but, unfortunately, like many other good things, it has in the race for novelties somewhat dropped out of cultivation. *C. Newellii* is a garden variety with deeper crimson flowers and perhaps rather larger trusses of bloom. In addition to being so useful for the conservatory the above may be recommended for cutting, as they will often give a supply when other flowers are scarce. If cut before the trusses of bloom are fully out the flowers will last fairly well. I think many flowers get a bad name for lasting through cutting them at a period when, if left on the plants, they would drop naturally. *Cestrum aurantiacum*, though not so free-flowering as *C. elegans*, is a desirable greenhouse plant, the large terminal corymbs of orange-yellow flowers being very effective. I find when struck from strong cuttings put in early in the spring and grown on in a cold pit during the summer, the plants if well exposed will not run up tall, but will make broad foliage and produce a large terminal cluster of flowers. I have had plants about 18 inches to 2 feet high which have proved very attractive. It will grow freely in any ordinary potting soil, but must be well exposed to the light and sun if it is desired to flower it in a dwarf state. A.

Bougainvillea glabra Sanderiana.—What is the right way of growing this? I have had plants three years, but I cannot get them to flower.—R. K., *St. Petersburg*.

Winter-flowering zonal Pelargoniums.—For producing a great quantity of bloom from November and on through the winter months I find nothing to equal the dark crimson-flowered *Henry Jacoby*. The way I secure the requisite number of plants is within the reach of everyone who grows this variety. This is simply to pot up the old plants as they are lifted from the flower beds in the autumn. The plants are first cut back into shape, any that are too leggy being rejected. They are then potted in ordinary compost and placed in a warm pit to break. This they do quickly, and form a number of new growths which soon flower and continue to do so all through the winter. *Daphne* is another

sort which is almost as free when treated in the same manner. I also grow a few other named sorts for autumn and winter flowering, but none are so free and satisfactory as the above two named sorts when treated in the way described.—A. W.

Impatiens Jerdoniæ.—This pretty Balsam is not often seen. It is very distinct both in growth and flowers. The peculiar inflated portion of the calyx is bright red, and is set off by the yellow portion of the flowers. The thick fleshy stems of a dark reddish brown are contracted between the joints, and each division has the appearance of a large brown slug. Some years ago I grew this and found it do well in an intermediate house. It may be propagated from cuttings early in the spring and will make nice flowering plants by the autumn. It does not form a great mass of bloom, but keeps up a succession for a considerable time. The chief point is to keep the plants free from thrips and red spider. It comes from the Neilgherries, and although it is classed with greenhouse plants, it makes more satisfactory progress when grown in more warmth and should be well exposed to the light. A rich loamy compost may be used, and as the plants begin to flower, liquid manure may be given freely.—A.

Pelargonium West Brighton Gem.—The above variety deserves all that is written of it on p. 455. For the flower garden I have grown it largely, and consider it one of the best for that purpose. Its habit is dwarf, and even in wet, sunless seasons *West Brighton Gem* retains its sturdy habit instead of becoming a mass of sappy growth, as is the case with some other varieties. It is free blooming from the time it is planted out till late in the autumn, even when the weather is not altogether favourable. For making masses of bright scarlet no *Pelargonium* is better than *West Brighton Gem*. I have found this variety invaluable for providing cut bloom through the winter as well as for planting out in the summer, and in a stock comprising several thousands of rooted cuttings there were always scarlet blooms to be had through the duller part of the winter. Grown entirely for the embellishment of greenhouse or conservatory, or for the furnishing of window-boxes and vases, there are few varieties of *Pelargonium* so useful as *West Brighton Gem*.—G. H. H.

Reinwardtia trigyna.—This is very useful for autumn and winter flowering. When well managed it keeps up a succession of its bright yellow blossoms for a considerable time, and these are well set off by the rich deep green foliage. It is now some time since I saw this in good condition, but some years ago it was a very popular plant in Sussex. It was, perhaps, more generally known as *Linum trigynum*. Cuttings root freely in the spring, and may be started in warmth and afterwards grown on in a cool frame. It hardly makes a good flowering plant the first year; plants that have been cut back and grown on the second year will flower very freely. It should be potted in good loamy compost, treated liberally early in the season, and then well exposed to ripen the wood in the autumn. Taken under cover about the first week in September, the plants will soon begin to flower. Red spider is its greatest enemy. I used to grow it in a shady position, but found if kept too moist the flowers were apt to damp off, especially if the old blooms were allowed to decay on the stems.—A.

Hoya carnosa.—A correspondent criticises (p. 434) a short note of mine on the above plant. If he will turn again to my note he will see that I did not give the particulars as representing well-grown plants from his point of view, but simply to show the accommodating nature of this *Hoya*. I certainly said that I never saw plants flower more freely or have finer trusses than these have produced for many years in succession, and I shall never expect to from plants grown on the lines laid down by my critic, viz., those of cutting away useful old wood to make room for the new.

Old flower stalks produce quite as large blooms as younger ones do and more of them on a stalk, and where the difference in prettiness or brightness comes in I fail to see. I probably had I grown the plants on the principles adopted by my critic I too might have had to bewail their loss through frost, but, knowing the dangers of the position they have to fill, I am careful to give only a limited root-run and to keep that full of roots; this and a careful supervision over the water supply during the winter have doubtless proved their safeguard more than once. The plants do, as my critic imagines, fill their allotted space, and to this extent I think I may claim them to be "well grown," especially as they flower very freely under the conditions given. Is my critic aware that this *Hoya* has been known to attach itself to a wall after the manner of an Ivy, and to grow and flower freely in such a position for years after the roots in the soil have died out? This, of course, could only happen in a house with a moist, warm atmosphere; still, the fact may be used as an object-lesson to show how little a part soil has to play in providing for the needs of the plant.—L. P.

NOTES OF THE WEEK.

Ionopsidium acaule.—I have now in flower in the open several patches of the pretty annual *Ionopsidium acaule*. I wonder it is not more grown than it is, as it makes a bright spot in the garden at this time of the year. It dies away in the summer, sows itself, and flowers in the autumn.—EDWIN CLEMENTS, *Caerleon, Killybeg, Dublin*.

Chrysanthemum Miss Harvey.—This, if small in flower, is one of the prettiest of the small decorative white kinds. The florets, as indeed the whole head, are rendered distinct by the splitting of the petals, that give a somewhat forked appearance to the flower. Judging by its size and its purity and freedom, it would be very useful as a late white.

Poinsettias.—In the warm conservatory just now these are much valued, and the finely-coloured bracts show to great advantage. In the sitting-room its chief drawback comes from the plant so quickly resenting a change of temperature, with which, if at all moist at the root, the leaves fall off rather quickly. By keeping the plants fairly dry at the root, the result is considerably modified.

Sweet Violets.—There is still an abundance of fragrant Violets to be gathered in the open, so remarkable has been the weather up to the present time. Rich in colour as well as perfume, with stems of remarkable length, we have no flower whose popularity is greater. A few bunches in a close, warm room emit a fragrance that pervades it to its utmost limits, a fragrance, too, of which one rarely tires.

Agathæa cœlestis.—The number of winter-flowering plants with blue flowers is very small, and of the few, this species cannot at all boast of large blossoms. It is not size altogether, but the quantity that so materially assists in making this an acceptable subject for winter work. The exceptionally coloured flower-heads come in considerable numbers, and a small handful placed in a specimen glass is very attractive.

Flowers artificially tinted.—The paper-white *Narcissus* is no longer "paper-white," because it has fallen on evil ways, and is now dyed by steeping the flowers through their stems in coloured liquids. This artificial colouring is both unnatural and repulsive, the amount of the pigment absorbed in some instances being quite double that in others. One can scarcely imagine why beautiful flowers are treated in this way.

Camellia alba plena.—It is probable that the demand for blossoms with long stems should have played its part in ousting the usually stemless flowers of this, and the formal *Camellia* now no longer finds its way into the best floral devices. As a flowering shrub in the conservatory, however, the plant is of great value. In some few places an assortment of *Camellias* is still grown, but the plants themselves are not great demand.

Cyclamen neapolitanum.—In the depth of winter in a walk round the garden there are few more pleasing sights than a good clump of *Cy-*

clamen neapolitanum nestling at the base of a Lilac tree. The zoned and marbled foliage is very glossy and looks bright among the dead leaves which lie among and around it. The leaves are set off, too, by the bright green Moss which covers the stones that edge the footpath adjoining.—S. AKNOTT.

Pelargonium Crabbe.—Among winter-flowering zonal Pelargoniums, perhaps no finer variety than this has ever been raised. It is indeed as remarkable in its fine form as in the colour, both being of the highest merit. The exact shade of colour presented is scarcely described in calling it a salmon-scarlet, for it is one of those intense shades that not only baffles description, but one which is at once singled out in a large and varying selection of the best kinds. It is very decided, too, the exact shade of salmon being very bright and pronounced.

Acalypha hispida.—It is not at all improvable, judging by the vigorous and generally hardy nature of this plant, that decorators will find it well nigh indispensable in winter-time owing to its free growth and the brilliant array of floral appendages. The effect of a large number of these coloured tails gracefully drooping over the handsome foliage is great. It is obvious, too, that the colour is long retained, as the variation was slight in the oldest and longest at the base and the youngest at the tips of the plants. Were it otherwise, much of the value of this remarkable plant would vanish.

Iris juncea.—The beautiful plate of *Iris juncea* and its variety *numidica* which appeared in THE GARDEN of December 10 should bring home to some the value of these flowers. *I. juncea* has with me the rather serious fault of making growth early and having its leaves injured by late frosts. From this cause I have lost it several times, and have finally given up growing it, as one cannot protect everything needing care at a season when these late frosts are most dangerous. No one who has ever bloomed the Rush-leaved *Iris* is likely to forget the beauty of its flowers.—S. AKNOTT, *Carslhorn, by Dumfries, N.B.*

Galanthus Olgae Reginae.—About three years ago a Snowdrop, which was understood to be *Orphanides' G. Olgae*, was offered under the above name. The price was, for a Snowdrop, rather high, and I only purchased one bulb. Unfortunately, although there are now three bulbs, I have not yet had a flower. Can anyone who has had this *Galanthus* in the United Kingdom give his experience of its behaviour with him? It is for one of its class, that of the autumn Snowdrops, a fairly good grower, but its non-flowering is a great disappointment. The glaucous line down the centre of the leaf, so marked a feature of this class of Snowdrops, is very pronounced in *G. Olgae Reginae*.—S. AKNOTT.

Jasminum nudiflorum.—Many plants of this on cottage and villa residences, where in the course of years they have assumed considerable size, are now gay with a profusion of yellow buds and blossoms. Some plants not many yards from where this note is being written cover a large space and will make a pretty picture for a long season. Too frequently when this is planted and trained to a wall or building, it is not allowed sufficient space to prove its worth. In other instances where years and a comparatively unrestricted growth have produced large examples, the plants yield their pretty flowers in plenty. The variety of winter-flowering shrubs is extremely small, and for this reason we should make the most of those we have.

Cypripedium insigne.—Few Orchids are of greater value than this well-known old kind, and where a good strain exists it should be encouraged. Its general hardiness, vigour, freedom of flowering, and simple requirements fit it for the amateur who has but little time at his disposal. A cool greenhouse suits it admirably, and during the summer months a partially shaded frame or pit is better still. With this treatment it is possible to retard the flowering very considerably

and secure a fine display of bloom in the depth of the winter season. The advantages on the side of cool treatment are considerable, not least being a good display of flowers about Christmas. Hardily grown throughout, the plants do not suffer in the same proportion when subjected to the uncongenial conditions of the sitting-room for a fortnight together, as do those grown in warmer structures. This is greatly in their favour, and should not be overlooked by those who would like to grow at least one Orchid that could be regarded with favour at flowering time.

Christmas Roses.—If any flower is deserving of popularity at this time it is surely the Christmas Rose, undoubtedly the most precious of winter flowers. No other hardy plant can possibly produce the same results as finely-established masses of this, the finest examples of which often yield a hundred or more blossoms each. But it is when the plants receive more than ordinary care, and the flowers expand almost without spot or blemish, that the blossoms as much as the plants in the open garden possess an even greater value. Isolated examples are best when the protection intended for them is given early. No plant has such a fine effect in a garden as this, and where specially grown and well suited, the masses of pure white, slightly cupped flowers are very effective. It takes time, however, and a soil specially deep and good to obtain the best results.

Luculia gratissima.—The warm greenhouse just now contains no finer flowering plant than this, with its splendidly formed heads of fragrant and delicately coloured blooms. Unfortunately, however, the plant is not always a success under cultivation and is rarely grown to a large size. Hence it is that so fine a subject for midwinter flowering is only seen occasionally, and then not in anything approaching specimen size. This is unfortunate, inasmuch as the largest heads of bloom are not usually produced on small plants. At the same time, with careful attention to cultural details, some very beautiful trusses of bloom result. Too often, however, the plant becomes a victim to excessive watering, a thing which above all else it cannot long endure. Good ordinary plants may be grown in pots of 12 inches diameter, with a third of this devoted to drainage. The airy conditions of a warm greenhouse are infinitely better than a moist stove for this plant, a splendid example of which may be seen flowering at Kew.

National Chrysanthemum Society.—A meeting of the executive committee was held at Carr's Restaurant, Strand, on Monday evening last. Mr. P. Waterer occupied the chair, and after the usual preliminaries were disposed of it was formally announced that the annual dinner was a decided success in every respect, and a vote of thanks was passed to the sub-committee responsible for its management. A report was submitted from the floral committee as to the dates of meeting for 1899. There was also a report submitted by the classification committee, dealing with the question of too-much-alike varieties and the classification of some recent novelties, particulars of which will appear in the society's new schedule.

Outdoor labels.—The system of labelling recommended by "M." (p. 488) is an extremely good one, but will not do for fruit trees when the latter are winter dressed with insecticides containing strong alkalis—at least, such is my experience. No matter how well the labels are written and afterwards varnished, such insecticides destroy the varnish; the writing then becomes less distinct and finally disappears altogether. For fruit trees the raised metal labels as now sold are I consider the best. I am about to replace a great many of the former which have become illegible with them.—A. W.

— In the number of THE GARDEN for December 17 "M." gives a suggestion for outdoor labels which in a large establishment where time and money are no object is no doubt all that

can be desired; but for the amateur, who perhaps requires two or three labels a week, the arrangement of emery paper, leather, ink, brush, and varnish is more than can be managed. Painted wood labels, of course, will not last, and the supports of the celluloid labels are too short without further support. To overcome the difficulty I have for the last four or five years used some zinc labels from M.M. Vilmorin-Andrieux and Cie., of Paris, which may be written on with an ordinary lead pencil, and so far last admirably and are not expensive. They require no preparation and are always ready for use. The most convenient size for me is 20 mm. wide and 150 mm. long. No doubt these labels can be obtained in England, but so far I have failed to find them in the catalogues; all the zinc labels quoted there seem to require special ink.—H. S.

The weather in West Herts.—The recent spell of warm weather, which had lasted for nearly three weeks, came to an end on the 19th. During this period there did not occur a single unseasonably cold day and but two cold nights. Since then the days have been much colder, while on the last two nights the exposed thermometer has registered respectively 8° and 5° of frost. The ground temperatures, however, still remain very high for the time of year, the reading at 2 feet deep being 5°, and that at 1 foot deep 3°, warmer than is seasonable. Rain fell on but two days of the week, and to the total depth of only about a quarter of an inch. For more than three weeks the wind has come almost exclusively from some southerly or westerly point of the compass.—E. M., *Berkhamsted.*

Sulphate of iron for Roses.—My employer has been told sulphate of iron is a good thing for Roses. Can you give me any information respecting the quantity to use for pot Roses and planted out in the house? Is it beneficial to Roses outdoors, and what is the best time to apply it?—R. A.

Name wanted.—I am very much obliged to Mr. Burbidge for the information he has so kindly given me about the Aroid that produces tubers on its leaf-stalks. From the tracing of the figure of *Pinellia tuberifera*, it is evidently the plant I was inquiring about, and of which a drawing was sent me from Ningpo. It seems curious that these tubers should grow from the middle of such slender leaf-stalks, though one can understand their growing from the axils of the leaves instead of ordinary buds. From what Mr. Burbidge says, this method of reproduction is by no means uncommon among Aroids. I expect that the leaf stalks in these plants partake really more of the nature of stems.—G. S. S.

Rats in vineries.—Mr. Burrell (p. 437) mentions the fact that in some gardens rats give much annoyance by burrowing through the arches from the outside to the inside border and taking the Grapes wholesale. In one garden rats had been troublesome, but on my taking charge new borders were made and fresh Vines planted. At first the roots were confined inside, but eventually the archways were cleared and outside borders made. Knowing rats to be numerous in the plantations around the garden, I felt some means must be adopted to exclude them from the vineries. I found an effectual remedy by fastening a double thickness of deep wire netting over the arches, letting it extend down to the drainage. This was no hindrance to the free access of the roots, and I never had a rat in the vinery.—J. CRAWFORD.

Names of plants.—*T. S.*—1, *Cupressus Lawsoniana* var.; 2, *Thuja occidentalis ericoides* (commonly called *Retinospora dubia*); 3, *Sequoia sempervirens* (Redwood); 4, *Thuja occidentalis*; 5, *Thuja gigantea* (Lobbi).—*Fritz.*—*Epidendrum cochleatum*.—*G. W. C.*—*Odontoglossum Ruckerianum* (good variety).—*Rector.*—*Bulbophyllum umbellatum*.

pans or baskets 6 inches across. The stems finish up in early autumn or late summer, according to the time they are started, this, where a number of plants are grown, keeping up a succession. Rest the plants thoroughly without going to the extreme of allowing the bulbs to shrivel, and bring them on gently at first, or but few flowers will be produced.

Dendrobium Johnsoniæ.—This beautiful species is occasionally seen, but it is a bad traveller, and many of the plants that have been imported have been so shrivelled that they must take some years to get really well established. A nice plant I noted during the week had five of the chaste-looking white blossoms, and these make one long for more. In habit it is intermediate between the evergreen kinds of the densiflorum class and the Australian kinds, but the flowers are all in favour of the latter. The blossoms are each about 4 inches across and pure white, with the exception of a few purple streaks about the inner side lobes of the lip. They occur eight or nine together on semi-erect racemes. *D. Johnsoniæ* does best in plenty of warmth, and should be planted in pans or baskets, these being suspended close to the roof. The plants usually commence to grow in late spring or summer, and the flowers occur upon the newly-made pseudobulbs. During the time they are growing and root action is going on they must be kept very moist, but they are better for a distinct rest after the flowers are past. This need not mean drying the plants up, but by giving a cooler house and rather drier atmosphere the eyes will remain dormant while still keeping plump. This is an Orchid of many names, but the above is the one under which it was first described. It was named *D. Macfarlanei* by Reichenbach after the Rev. S. M. Macfarlane, who sent plants to Messrs. Veitch in 1882.—H.

Gongora maculata.—Though seldom seen, this species is very interesting, and in its better forms showy enough to be included in all collections. The flowers are produced on pendulous racemes at various times in the year, and vary in colour from yellow to pure white, being usually spotted with red. The bulbs are strong and deeply ribbed, light green, and bear stiff lanceolate leaves. *G. maculata* is an easily grown plant, which from the direction taken by its spikes looks best when grown in baskets. These should be well drained, when the compost need not be disturbed for several years, the plants being more free-flowering in this way than when frequently pulled about. Spring is the best time to renew or add to the compost, this consisting of good fibrous peat, Sphagnum, and a little nice clean fibrous loam. The roots when the plant is healthy are so freely produced, that they frequently push not only right through the compost and drainage, but upward and outward into the congenial air of the house. It likes a very moist atmosphere, plenty of water at the roots, and frequent light dampings overhead when the weather is fine. The temperature of the *Cattleya* house suits it well, though a few degrees higher does no harm. Plenty of light the whole season is advisable, but scorching of the foliage is, of course, to be avoided. *G. maculata* is a native of Demerara, and was introduced in 1832.

Cirrhopetalum picturatum.—This species is a good instance of the peculiar form so common in the genus, the umbel of flowers sustained on a wiry stalk about 6 inches in height. Each flower is about 2 inches in length, the prevailing colours being dull red and green. It is by no means common, though it has long been in cultivation. Its treatment is not particularly difficult, but it requires care beyond the ordinary if the best results are looked for. Being of rather dwarf habit, the receptacles for it must not be very large, nor is much compost needed. Fine plants may be reared on wooden rafts, such as are often used for the Mexican *Lelias*, and on this a thin compost consisting of peat fibre and Sphagnum Moss must be firmly placed, the plants being wired down to this and all ragged ends removed,

As the plant extends new compost may be given, and thus disturbance of the older roots will not often be necessary. The best place for it is a light position in the East India house, suspended near the roof-glass if possible. This ensures a solid yet quick growth, and if carefully treated as autumn draws on, it will flower freely. It requires very little water after the growth is finished, many plants having been ruined by giving too much at this season. *C. picturatum* is a native of Burmah, and has been found in various parts of the country by different collectors since first it was introduced in 1840.

Zygopetalum Mackayi.—In writing of this fine winter-flowering plant, I mean the one usually known in gardens under this name, a name that some botanists say belongs rightfully to a rare and almost unknown species. Its great merit, of course, lies in the fact of its flowering in winter and lasting over so many weeks in full beauty; but no matter when these fine flowers are produced, no one can help admiring them, the pretty blue of the broad, handsome labellum contrasting well with the more sombre brown and yellow of the sepals. The cultivation is not difficult, one of the chief points being cleanliness, as the soft foliage and bulbs when young are very apt to be attacked by brown scale, a pest which, though easily got rid of, is sure to leave its mark behind after a severe attack. The bloom-spikes appear in the centre of the young growths, and as the plant is therefore growing and flowering at the same time considerable moisture is necessary, though it is often dull, cold weather at the time. If the plants flower at the same time as *Calanthe Veitchi* and others of this class, the *Zygopetalum* has a very fine appearance when associated with them, and many a pretty winter picture might be produced with these two plants. It requires a good sound compost and a liberal addition of clean fibrous loam and leaf-mould, and the usual Orchid compost is greatly relished by the large fleshy roots. The plants dislike being disturbed, and it is important that they be kept in good health, for if once they get into bad condition they are bad to bring back to a satisfactory state.—H.

RESTING ORCHIDS.

THE term "rest" as applied to Orchids is one often misunderstood. To many novices in their culture it means simply a withholding of the water supply and a lowering of the temperature. But it is more than this. Rest is not, perhaps, the exact term to use, and recuperation is quite as unsuitable. It is a cessation of growth as far as outward appearances go, but the economy of the plant is, of course, still going on. If all Orchids were alike in their needs, the resting season would be a very easy time for the cultivator, but they are not, and for this reason the grower must still be on the alert and give to each plant the attention it needs. Pseudobulbous species, as a rule, take a dry rest, though there are exceptions to the rule, and some like a longer resting season than others. Evergreen bulbous species, too, rest, but these in the majority of instances require a little moisture the whole year round, the quantity depending upon the habit of the individual kind. Although the present is the quiet season for most Orchids, there are a few kinds that are growing freely while others are just beginning to be active. While the majority, then, are kept cooler and drier, these will need to be more or less encouraged. As a well-known example we may take *Cypripediums*. Often when the flowers are open these plants will be stood about in draughty conservatories and rooms, but if the cultivator would look at the plants he would see that these have not only the strain of flowering to keep up, but many of the species are already in full growth. Yet the plants are exposed to the very worst conditions possible

for them. This is too obviously wrong to need comment. As a general rule the species and hybrids of *Cypripediums* that flower during the winter months are comparatively quiet during the late summer, and it is only reasonable to let them rest then. The flowering is the commencement of the active season, and this should be kept in mind. The cool house at this time of year contains quite a large number of Orchids that are growing. Some grow more or less all the year, as the *Odontoglossums*, others, as *Cattleya citrina*, are in the middle of their season and will rest later, while there are always some individuals among those that should be at rest which have not made up a proper growth and require a little more time. To sort these out, and I have only mentioned a very few, will be the work of the cultivator now. In some instances it will perhaps be necessary to group the resting plants at one end of the house and those in growth at the other, while, of course, the watering will have to be very judiciously carried out. But only in a very few cases is a perfectly dry régime required, and it is well to remember that even these are not dead sticks, but living plants.

Dendrobium bracteosum.—Although the individual flowers of this species are very small and insignificant, they are very freely produced in dense racemes, and thus the plants make a pretty show. It is a fairly strong grower, the stems on strong plants being about a couple of feet high, strictly deciduous, the flower-spikes appearing at the upper part of these. In colour the flowers are a pretty soft rosy purple, and it is worth growing where curious and interesting species are liked. The plants may be placed in medium-sized pots or baskets suspended from the roof with the other deciduous kinds while making their growth, and a short season of rest is usually needed. Besides the type, the white form, *D. b. album*, is well worth growing.

Cymbidium Tracyanum.—Some fine forms of this rare species were shown at the Drill Hall on December 13, the one included in Messrs. Veitch and Sons' group being especially good. It is a fine, handsome plant, and seems to be turning up oftener. In habit it is very like *C. Lowianum* and *C. giganteum*. The spike referred to had eleven flowers, large and bright in colour. The sepals were broad and substantial, the pretty yellow and crimson lip lighting up the whole flower and giving it a much brighter appearance than in *C. giganteum*, which it most closely resembles. It thrives well with the other kinds named in the cool house, and, like them, requires a free and open yet substantial compost, the roots being strong and vigorous. In all essential details the treatment is the same as advised for *C. giganteum*.

Seedling Cypripediums.—Hybridisers have now quite mastered the art of raising seedling Orchids and *Cypripediums*, and the flowering of hybrid plants is now looked upon as a very common occurrence. The time the plants took to flower is much less than formerly, but I should think the *Cypripedium* shown at the Drill Hall by Mr. R. I. Measures, of Cambridge Lodge, Camberwell, on December 13 is about a record for time. The plant shown was a typical one, strong, fresh and healthy looking, and was raised by Mr. H. J. Chapman from *C. callosum* and *C. leucochilum*. The seed was sown on January 26, 1896, and the plant opened its first flower on December 6 of this year, so that it is well under three years. As far as the bloom is concerned, it is a very pretty one, and a good deal like *C. Wottoni* (*C. callosum* × *C. bellatulum*), which was shown in the same group.

Phalænopsis amabilis.—Very lovely now are the racemes produced by this splendid Moth Orchid, and though many growers in the neighbourhood of London would rather they flowered at any other time, those in the country have no

such cause for regret. Although it can hardly be said that this species is as easy to grow as any Orchid, it is certainly one of the best, if not the best, of the genus to cultivate. The plants must never be left to take care of themselves, so to speak, as may sometimes be done with deciduous kinds that take a long dry rest. They require watchfulness and care the whole season through, or the results will be poor. It is true the plants have an active season and one of comparative inactivity, but these are not so sharply defined as are those of the kinds with which I contrasted it. They may, it is true, be recognised by the grower, but a plant will occasionally enter the resting season with a leaf half formed, and though all experienced growers would rather see the full leaf, no good will follow trying to make the plant complete it. The seasons must glide in and out of each other, so to speak, and then the plants get injured to the altered conditions. *P. amabilis* likes rather more root room than the majority of Moth Orchids, and though disliking closeness of material as much as any, the roots will push through and ramify in a fair thickness of nice clean fresh Moss. Disturbance is of course unavoidable now and then, but it should not be oftener than absolutely necessary, and plants grown in wood baskets may, by carefully removing piecemeal all old and sour material and adding new, be left in these until they decay from the moisture in the house.—H.

KITCHEN GARDEN.

EARLY POTATOES FOR SHELTERED BORDERS.

In some notes on early Potatoes in *THE GARDEN* reference was made to the old, but good, Gloucestershire Kidney. For many years I grew this variety, but have discarded it of late years for heavier croppers. For years I grew the Ashleaf section for first crop in the open, but a failure caused me to try the early Puritan type. Much depends upon the wants of the grower. In a late, cold, dry spring the Ashleaf kinds cannot be termed heavy croppers. To lift a bushel or two of tubers daily as early in the season as possible, it is desirable to have good croppers. When in Devon, Alma was my favourite early variety. This in shape is not unlike Sharpe's Victor, but more kidney-shaped. No variety I have ever grown has been of better quality, but of late years on a light soil the crop has been poor, and I have been obliged to discard it. The same remarks apply to Sharpe's Victor, a fine forcing Potato, but in a light soil in the open borders the crop during three or four dry seasons failed. Sharpe's Victor from the first was a great favourite on account of its earliness and good shape. For frame or pot culture its small top makes it most suitable. The Ashleaf when cooked do not lack flavour, and this will atone for loss of crop when large quantities are not needed early in the season. Veitch's Ashleaf is a good type. This with me makes less top than the Hammersmith, but the latter is still one of the best in cultivation. Myatt's is likewise a grand Potato, the tubers being larger than in either of those named, but it is so subject to disease that I have been obliged to discard it. For earliness, so far none has surpassed Ninety-fold. Last June this was the best Potato both in crop and quality. I consider this new variety a splendid acquisition in every way, and its table quality is so pronounced, it will, I am sure, become a general favourite. For some years Harbinger was my earliest Potato, then Ringleader took its place, and I am inclined to think Ninety-fold will surpass Ringleader. Still, seasons vary, and I am not inclined to give up Ringleader. I still grow Ringleader in frames, but this season am giving the newer one a place by its side to test earliness. For quality and crop English Beauty is a general favourite. This I plant on open borders, whilst those noted above have a more sheltered position. English Beauty is the result of crossing Myatt's with Beauty of

Hebron. Its only fault is that unless lifted early it is somewhat subject to disease. For quality I have never had a better Potato than Sutton's A1, but in a dry soil it does not crop so freely as Ninety-fold. Sutton's A1, a round tuber, or nearly so, is one of the earliest of all, and boils dry. There are none that crop so well as the American kinds, of which Early Puritan is the type, but in wet seasons the tubers are liable to disease. S. H. B.

Winter-sown Onions.—"A. D.'s" note on the advantages of sowing Onions in January under glass and transplanting to the open garden when large enough is well worth notice. On shallow, hot soils especially, this plan should be practised. A friend of mine having such a medium to deal with tried sowing early in the year in boxes and transplanting in April. Previous to this his Onions had always been much thinned and sometimes spoilt by the maggot. The transplanted bulbs, however, escaped and grew away freely, making fine solid, good-keeping specimens. After that he always grew his Onions in that way. At first the labour may appear great, but in reality it is less than that incurred by the usual way of sowing in the open and thinning out, and loss and disappointment are saved.—N.

—Onions and their cultivation constitute just now perhaps a somewhat stale subject, but the present moment is all the same one of interest to all those growers of these bulbs, and they are now legion, who sow seed under glass in midwinter to secure fine plants to put out in the spring for the production of big bulbs. Sowings are usually made in shallow pans, well drained, in light and sandy soil, having in it a good proportion of fine leaf-mould. In this material the seeds, just buried and the pans stood in a temperature of from 55° to 60°, germinate soon, and if the pans be then placed near the glass, growth is also very sturdy. When stood too far from the glass the seedlings are apt to draw, then fall over, and in such condition fail to make strong plants later. When the little plants are about 3 inches in height, they should be carefully lifted from the seed-pans and be pricked out 2 inches apart into other pans or shallow boxes, the soil now including two parts turfy loam, as greater root-fibre is thus induced to form. After going through a process of hardening by exposure to more air in a cold frame, transplanting, by lifting each plant with a small ball of soil and roots with the aid of a trowel, should take place towards the end of April. After-results will then depend on the way the ground has been prepared and the culture.—A. D.

Pea Duke of Albany.—To me this has always been a very disappointing Pea, though my experience of it has been obtained in gardens in Hants, Somerset, and Wilts. It produces very fine pods, in fact I know of no other that can excel it in this respect; but this avails but little when the lightness of the crop is taken into account. It is very subject to mildew, and a spell of hot summer weather arrests its growth, seriously reduces the crop, and causes half-filled and deformed pods quite out of proportion to what is expected. In some soils I have on some few occasions seen perfect crops of the variety, but I have never been fortunate enough to succeed with it, and do not now depend on it. There are certain soils that suit it, no doubt, for I observe it is frequently referred to by many growers who have recorded their experience of late in *THE GARDEN*. The Duchess, which has been claimed as an improvement, has not proved in any way superior to Duke of Albany in my case, and has shared the same fate. Had I the convenience and time to deeply trench the ground for Peas possibly a different verdict might be given, but as this is impossible, varieties of stronger constitution are chosen.—W. S.

Seakale.—That it is possible to have good blanched Seakale early in the winter was evidenced at a show held at Twickenham on No-

vember 15 last, when Mr. W. Poupart, one of our greatest market growers of this vegetable, staged a bundle in first-rate condition. How he succeeded in getting crowns to ripen off so early as October I do not know, but then he habitually has Seakale so early as this date and in considerable quantity. Several years since Mr. Poupart mentioned that he forced annually the product of sixteen acres of roots—an enormous quantity, rendering it needful to start early in the winter. The forcing is done in brick pits having hot-water pipes running through them. These pits do not rise above the ground line, and when filled are covered up with boards and a thick coating of long litter. With reference to the point raised by "W. S." with respect to the difficulty in getting crowns to mature their leafage sufficiently early, especially during such a season as the past, I should like to ask what effect in promoting early maturation is produced by early winter planting? No doubt it is the rule to collect root cuttings during the winter, lay them in thickly, when they callus over top and bottom, and then plant in the spring. That some must be so treated is inevitable, unless every mature root be trenched out, trimmed, and laid in in November. Then the root cuttings may be planted at once. I am not in a position to say whether the effect of earlier planting would be to promote earlier leafing and autumn ripening or not.—A. D.

OXALIS CRENATA AS A VEGETABLE.

As attention has once more been drawn to this interesting and beautiful flowered Peruvian plant by a basketful of its edible tubers being sent to the fruit committee of the Royal Horticultural Society at its last meeting at the Drill Hall on Tuesday, the 13th inst., by Mr. C. Herrin, of Dropmore, it may interest some of your readers to whom the plant as a useful table vegetable is new and unknown to hear what one of the great authorities on English horticulture, Mr. Sweet, says about it in the second volume of the second series of his beautifully illustrated work, "The British Flower Garden," published in 1833. After a charming picture of a bunch of its beautiful deep yellow flowers, which are prettily and distinctly veined with purple lines radiating from the centre, and exceedingly ornamental, he writes on p. 126 as follows: "This plant is remarkable for the singular enlargement of its subterranean stems which closely resemble the tubers of the Potato. [This is hardly true now, as from woodcuts in Nicholson's "Dictionary of Gardening" and description in *THE GARDEN*, they much more closely resemble the tubers of *Tropaeolum tuberosum*.] It appears to be what is termed a progressive annual. The flowering stems die annually, root and all, when the tubers are found entirely separated with a portion of the filiform attachment adhering to them. By these the plant usually appears to increase itself, for it rarely if ever perfects seeds at least in this country, the colder climate of which may favour the production of tubers. The tubers are produced in considerable plenty, and are often 2 inches long by 1 inch in diameter. When raw they are slightly sub-acid, but on being boiled they entirely lose this flavour and taste very much like the Potato, for which they might form occasionally an agreeable substitute at the tables of the curious. It is a native of Peru, and is cultivated largely in the gardens about Lima as a salad, for which purpose its succulent stems and acid flavour seem strongly to recommend it. It grows freely in the open border and is readily increased by cuttings as well as by the tubers, which require to be taken up and treated as Potatoes." It is curious that Jacquelin, though he mentions this species in his "Oxalidum Monographia," and devotes an entire page to its description, does not figure it.

W. E. GUMBLETON.

Late ripening of Seakale.—Gardeners in the midland and northern counties will probably

not be so far behind their southern brethren this winter with their first batches of forced Seakale. As a rule, my breadth of yearling roots in South Notts was quite a fortnight later in shedding its foliage than similar lots nearer London, and, as "W. S." asserts, it is a loss rather than a gain to lift and subject to warmth crowns from which the leaves have to be cut off. Unless a strong heat is given they remain inactive for weeks, and applying strong heat generally means stunted growth with poor flavour. When pushed for time, I have sometimes placed some half-dozen crowns in pots, covering them with other pots, standing them on boards over hot-water pipes in a Pine stove. Although time has been gained, quality has been lost, unless in the case of extra large, well-ripened crowns.—J. C.

Endive, Fraser's Broad-leaved.—In looking through the kitchen garden calendars I have never seen the above variety of Endive mentioned. I wonder at this, as without doubt it is one of the most reliable and best of the broad-leaved section and of delicate crisp flavour. It is now many years since its introduction, but I still prefer it to all others. In trying winters it is not so easily injured by damp and frost and keeps in the frames or pits late in the spring without running to seed. Some varieties need removal to a dark structure, such as the Mushroom house, to blanch during the dull, dark days of December, as if covered with mats in the pits the centres are apt to partially decay. Fraser's, however, stands this very well; in fact, its suitability for rough-and-ready treatment generally is one of its chief recommendations.—J. CRAWFORD.

Thinning out Seakale.—Good cuttings, after callusing is completed, will form as many as eight or nine shoots, and it has been my practice to rub off half of these at planting time, further reducing the number to the three stoutest as soon as growth has far enough advanced to distinguish them. Some growers who know the value of extra strong crowns leave only one growth on, and this is quite justifiable where there is ground enough at command for the accommodation of perhaps several thousand roots; but where the most has to be made of the ground, gardeners cannot afford to dishub thus rigidly. In some places where only a small bed of permanent roots is forced it is still done by means of pots and leaves, and in the case of limited quantities there is no advantage in dissuading growers from this method of forcing, as by no other means can such crisp, well-flavoured Kale be secured. Amateurs, however, need reminding of the necessity of summer thinning of the crowns.—NORWICH.

Extra early Cauliflowers.—"S. H. B." has a good word for Mont Blanc Cauliflower, and recommends it for planting for early cutting. If by planting this variety in handlights in October, or even in March, after protecting in frames through the winter, useful heads may be had by the end of May, it will certainly be an acquisition, for, as "S. H. B." remarks, Cauliflowers are none too plentiful at that date, and that once reliable variety Early London is, according to my experience, very uncertain nowadays. I am rather surprised that "S. H. B." does not name Early Snowball, as I think that, given a true stock, it is still a grand Cauliflower for early cutting, the heads being of a nice size and colour for the dining room. It was much in request at one time, and I expect, owing to this fact, the strain deteriorated and is now seldom obtained true. With me in a light soil the small forcing sorts always buttoned badly, for which reason I discarded them.—NORWICH.

Pea Ne Plus Ultra.—The notes on Peas which appeared in THE GARDEN from all parts of the British Islands were interesting and instructive, because from them might be gathered the different methods adopted for keeping up a supply of this important vegetable over a long period. I read the notes as they appeared week by week, and one thing that struck me as being worthy of remark was the general popularity of a few well-tried varieties,

and amongst them the old favourite Ne Plus Ultra. It is needless to describe it, as it is so well known, and the fact that it is grown and spoken well of by a large percentage of those who have assisted in compiling the notes is evidence that it is one of the best main-crop Peas in cultivation. The instances in which Ne Plus Ultra is not mentioned are few, and when we come to consider that the reports come from all localities, comprising marked differences of soil and situation, we realise how accommodating this old sort is. In spite of the contention that varieties of vegetables deteriorate, and in spite of the fact that recent years have seen the introduction of many good sorts, Ne Plus Ultra holds its own, and from the evidence of a large number of practical gardeners, the inference may be drawn that this old favourite is amongst the most popular Peas at the present day. Perhaps one of the greatest points in its favour all along is the way in which it keeps up its true character. Now and then one sees inferior forms of it, but considering the generality of its cultivation, Ne Plus Ultra shows very little deterioration. Another fact is evident from the notes on Peas, namely, that quality always lasts. There have been numerous varieties of Peas introduced which are not mentioned, but those possessing good all-round qualities need only to be grown to make a lasting reputation.—G. H. H.

WINTER SPINACH IN DRY SEASONS.

SPINACH, and especially autumn-sown, is more easily affected than many crops both by lack and excess of moisture. Many gardeners having a heavy, retentive soil to deal with know the liability there is of winter breadths becoming affected and even ruined by the yellows in wet seasons, even when the ground is quite free from wireworm. Beds which up to a certain time the gardener has had reason to be proud of suddenly go off without the slightest warning. On the other hand, to sow winter Spinach in parched ground is to court failure, as the seed germinates slowly and weakly, a patchy plant only is secured, and the plants never seem to strengthen satisfactorily even when rain does come. Position is a great thing in dry seasons, and I have seen excellent results from sowing on an east border. Here the plants grow hardy, and moisture being better retained than on open quarters the plants do not run to seed so early in spring. Where, however, open quarters are unavoidable, I prefer in autumns like the one just past to sow on a plot from which Tripoli Onions have been cleared, merely clearing off weeds and rubbish and drawing the drills a little deeper than usual. These should be filled with water twice over, allowing an interval of a couple of days, after which the seed should be sown rather thickly, and after the drills have been filled in, a liberal quantity of old Mushroom manure sprinkled over them and a gentle watering given with a rosed watering-pot. This will cause the seed to germinate and support the young roots until rain comes. The surface can then be pricked over for neatness sake, when, if thinning the seedlings is not too hurriedly or too rigidly performed, a good crop of Spinach may be looked for. That a warm, sheltered south border is not the best position for winter Spinach I have more than once proved, the plants sooner suffering from inclement weather than when growing in more open, exposed positions, being in the latter more hardy. My experience is that the summer Spinach is equally as hardy as the prickly or so-called winter variety, and I have found it a good plan to sow a breadth of each, as sometimes one does better than the other. Fish manure or guano is excellent for Spinach.

J. CRAWFORD.

Kohl Rabi.—In a hot, dry summer this vegetable proves most servicable. I admit as regards quality one cannot compare Kohl Rabi with a well-grown Model or Snowball Turnip, but in hot, dry summers Turnips are none too plen-

tiful, and Kohl Rabi in my opinion is far superior to a poor Turnip. When served at table mashed in the same way as Turnips, Kohl Rabi is a palatable vegetable, and the roots have a peculiar sweet flavour. Seed sown in April and May in drills 15 inches to 18 inches apart will give good dishes through June till August. This plant does well in poor, dry soils.—S. M.

Pickling Cabbage.—It is usual to sow the varieties of pickling Cabbages in July or August and to plant them out with the ordinary cooking sorts in autumn. On good ground they often grow to a gigantic size, and if not cut early are liable to split. As a rule they are not asked for for pickling until a few frosts have occurred, being then considered in better condition. I have seen a whole row spoilt by splitting. A few years since I sowed the red sort in a Carrot frame in February, and although the heads did not attain the size autumn-sown ones did, none of them split. Since then I have been in favour of spring sowing. There are now various sorts of pickling Cabbages, but perhaps none better than the old Red Dutch.—B. S. N.

Early forcing Turnip White Gem.—This is one of the best for frames. Last season it was grown alongside Early Milan, and though not earlier than this, it is, in my opinion, of better quality. In this latter respect it more resembles Early Snowball, one of the best early Turnips for the open ground. The newer variety is oblong in shape and has pure white, particularly sweet flesh. Sown early in January it will give handsome roots in April. For first crop in the open White Gem is specially suitable, as it matures so quickly. In heavy land this variety will be valuable, as it does not run so quickly as the flatter-rooted varieties. In dry seasons I have noticed the flavour of this kind of root is always superior to that of the flat-rooted kinds.—G. WYTHES.

Parsley in winter.—In gardens where sufficient rainfall enabled midsummer-sown batches to make headway, Parsley will, owing to the mild weather at present prevailing, be plentiful and good. Gardeners, however, must not be caught napping, or with a sudden visit of sharp weather the supply may speedily dwindle. It is not snow that injures it, as, provided there is a sufficient depth to cover the leaves and crowns, it acts as a protector rather than otherwise, but keen, frosty winds soon cause it to droop and become discoloured. Where pit room is plentiful it is a capital plan to sow a few lights at the end of June or early in July for winter use, this plan being even better than lifting from the open and transplanting under glass. Where, however, the latter course has to be adopted, transplanted roots are best for the purpose, as they have not such long tap roots and consequently lift better. It being next to impossible to have too much Parsley in winter and spring, open-air rows should be arched over with rods so that protection can be given.—B. S.

Mercury as a vegetable.—This will grow where Spinach fails. In Lincolnshire and the surrounding counties Mercury is found in most gardens, and is valued on account of its hardiness. The plant when once established lasts for many years, but much better results are secured if the roots are divided up every three years and given new quarters and good culture. Seeds should be sown early in April in rows 15 inches apart, allowing about half that distance between each plant in the row when thinned. The following spring, as early as possible, it will be advisable to give more space by lifting every other plant in the row and making a fresh bed. The young shoots early in the spring make a good vegetable if cut like Asparagus. When grown for this purpose the plants may be covered with a good thickness of old leaf-soil or spent manure in the winter. The shoots are then blanched and cut in a young state. It is not well to cut too hard the first season. I have found it advisable to have two or three beds, so as not to cut one lot too severely at one time.—S. H. B.

THE ORCHARD BEAUTIFUL.

THE spirit of beauty must have been at the birth of the trees that give us the hardy fruits of the northern world—Crab, wild Plum, Pear and Cherry—yielding back for us in their bloom the colour of the clouds, and lovelier far in their flowers than Fig or Vine of the south. The old way of having an orchard near the house was a good one. Planted for use, it was precious for its beauty, and not only when the spring winds bore the breath of the blossoms of Cherry, Plum, Apple, and Pear, as there were the fruit odours, too, and the early Daffodils and Snowdrops, and overhead the lovely trees that bear our

be looked for of an orchard in which the beauty of all our hardy fruit trees would be visible? If we consider the number of distinct species of fruit trees and the many varieties of each, we may get some idea of the pictures one might have in an orchard, beginning with the bloom of the Sloe and Bullace in the fence. The various Plums and Damsons are beautiful in bloom, as in the Thames valley and about Evesham. The Apple varies much in bloom, as may be seen in Kentish and Normandy orchards, where the flowers of some are of extraordinary beauty. The Pear, less showy in colour, the Medlar, so beautiful in flower and in foliage, and the

main, Beauty of Kent, Blenheim, Cellini, Emperor Alexander, Flower of Kent, Golden Noble, Hawthornden, Kentish Fillbasket, Reinette du Canada, Warner's King, and Yellow Lustre. Some Apples, too, bloom very late, this being the case more particularly with some of the cider Apples both of England and France, which bloom in June in Sussex; but any Apple grown for its fruit is sure to be worth having for its beauty.

POOR SOIL SHOULD NOT HINDER.—In the planting of the orchard beautiful some may be deterred by the idea that the soil is too poor, and no doubt it is a much simpler matter on the good fruit tree soils of Devon,

Hereford and Kent than in other districts; but the difference in soils is no reason why some counties and districts should be bare of orchards, and in many the soil is as good as need be.

Indeed, in the country south of London, as in Kent, where much of the land is taken up with orchards, we may notice the trees suffering much more from drought in dry years than they do in the good sandstone soil of Cheshire or in Ireland and Scotland, where there is a heavier rainfall. Few of our orchard trees require a very special soil, and where chalky or very warm soil occurs, the best way is to keep to the kinds of fruit it favours most. However poor the soil, there are certain fruit trees that will do well on it if we take care to preserve them from drought. But though the orchard beautiful must be of trees in all their natural vigour, and of forms lovely in winter as in spring and summer, the trees must not be neglected, allowed to perish from drought, or become decayed from

In a Devonshire orchard.

orchard fruits—Apples, Pears, Cherries, Plums, Medlars, Damsons, Bullaces, and Quinces. To make pictures to last round the year, I should ask for many of these orchard trees on a few acres of fair ground, none the worse if too hilly for the plough: a belt of Hollies, Yew, and Scotch Fir on the cold sides to comfort trees and men; with careless garlands of Honeysuckle, Rose, and fragrant Clematis among them here and there, and in the fence bank plenty of Sweet Brier and Hawthorn. If we see fine effects where orchards are poorly planted with one kind of tree, as the Apple (in many country places in our islands there are no orchards worthy the name), what might not

Quince, so pretty in bloom in Tulip time, must not be forgotten. The Cherry is often a beautiful tree in its cultivated as well as wild forms, and the Cherry orchards in parts of Kent, as near Sittingbourne, are pictures when in bloom. There is no better work in a country place than choosing a piece of good ground to form an orchard; and, considering the number of trees that are worth a place for their beauty as well as their fruit, a dozen acres are not too much in a country place where there is land to spare.

The bloom of all our fruit trees of native origin is beautiful, and even among these we find variety, and among the most beautiful Apples as regards blossom are Adams' Pear-

ing, scale or other pests, and it should be the pleasant care of those who enjoy their beauty to protect them from all such dangers. The idea that certain counties only are suited for fruit growing is erroneous, and even if it were true, the fact need not deter us from planting orchards of the hardier trees and of good local kinds. Much of Ireland is as bare of orchards as the back of a stranded whale, but who could say this was the fault of the country? Mr. Burbidge has so lately told us of the fine Cherry orchard near Bray, that I need not give other instances.

THE TREES TO TAKE THEIR NATURAL FORMS.—Where we plant for beauty we can have no choice for any but the natural form of the

tree. Owing to the use of what are called dwarfing stocks and like contrivances, fruit gardens and orchards are now beginning to show shapes of trees that are not beautiful compared with the grand old orchard tree. However much these dwarf and bee-hive shapes may appeal to the gardener in his own domain, in the orchard beautiful they should have no place. For the form of all our fruit trees is very good indeed, winter or summer, and that is a great point if we seek beauty. We know what the effect of flower-time is in the pictures of such painters as Mark Fisher and Alfred Parsons, if we have not taken the trouble to see the finer pictures of the orchards themselves, seen best, perhaps, on dark and wet days in flower-time. Lastly, the effect of finely-coloured fruit on high trees is one of the best in our gardens. Therefore, in every case, whatever pruning we do, let the tree take its natural form, not only for its own sake or the greater beauty of natural form generally, but also for the variety of form we get even between the varieties of trees of the same species.

Clearly if we prune to any one ideal type of tree we can never see the interesting variety of form shown by the varieties of one species, as the Apple and Pear. Keeping to the natural form of each tree, moreover, does not in the least prevent thinning of the branches where overcrowded—the best way of pruning.

CIDER ORCHARDS are often very picturesque in the west of England and in Normandy, and so long as men think any kind of fermented stuff good enough for their blood, cider has on northern men the first claim from the beauty of the trees in flower and fruit, and indeed throughout the year. The cider orchard also will allow us to grow naturally-grown trees and those raised from seed. Even in countries where they do not grow fruit for its own sake, we may see very beautiful effects from the trees in cider orchards. These cider orchards are extremely beautiful, and the trees in them often take fine natural forms. They have a charm, too, in the brightness of the fruit, and also a peculiar one in the lateness of the blooms of some, many of the cider Apples flowering later than the orchard Apples. In some cider orchards near Rouen (Lyons-la-Forêt) I saw the finest, tallest, and cleanest trees were raised from seed. The owner, a very successful cider grower, told me they were his best trees, and raised from seed of good cider Apples. If he found on their fruiting that they were what he wanted as cider Apples he kept them and was glad of them; if not, he cut their heads off and regrafted them. These were free and handsome trees with good grass below them, just like the Cherry orchards in the best parts of Kent, where the lambs pick the early grass. But however beautiful such an orchard, clearly it will not give us the variety of form and beauty found in the mixed orchard, in which Cherry, Apple, Plum, Pear, Medlar, Quince, Walnut, Hazel and Mulberry take a place; there also the various interesting trees allied to our fruit trees might

come in, such as the true and common Service tree, Almond, Cornelian Cherry, Hickory, and Crab.

GRAFTING.—Where we make use of grafted trees—and generally there is no choice in the matter—we should always in the orchard use the most natural stock that can be obtained. It is much better, for instance, to graft Pear trees on the wild Pear than on the Quince, a union harmful to the Pear on many soils. If we could get the trees on their own roots without any grafting it would often be much better, but we are slaves to the routine of the trade, and anyone who asks for a fruit tree on its natural roots is regarded as a wandering lunatic. The history of grafting is as old as the oldest civilisations—its best reason, the rapid increase of a given variety. In every country one or two fruit trees predominate, and are usually natives of the country, like the Apple in Northern Europe and the Olive in the south. When men found a good variety of a native fruit they sought to increase it in the quickest way, and so having learned the art of grafting, they put the best varieties on wild stems in hedgerows, or dug up young trees and grafted them in their gardens. The practice eventually became stereotyped into the production of the nursery practice of grafting many varieties of fruit trees on the same stock, often without the least regard to the lasting health and duration of the tree so grafted. In some cases when we use the wild form of the tree as a stock we succeed; but grafting is the cause of a great deal of the disease and barrenness of our orchards and fruit gardens, and we should advise everybody to get out of it a little if they can. It is now possible to get some Apple trees on their own roots, and in France, and here and there in England also, some kinds of Plums in that way. Where we graft, it is important to graft low; that is to say, in the case of cider Apples, for example, it is much safer and better to take a tree grafted close to the ground than grafted high up, as is commonly practised, as the high graft is liable to accident and does not make so fine a tree. In the orchard the good old practice of sowing the stone or pip of a fine fruit now and then may also be followed with interest.

STARVED ORCHARDS.—Even in the good fruit counties like Kent one may often see in any year orchards starved from want of water, and the turf beneath almost brown as the desert. Where manure is plentiful it is well to use it as a mulch for such trees, but where it is not, we may employ various other materials for keeping the roots safe from the effects of drought. Not only the tree roots want the water, but the roots of the competing grass suck the moisture out of the soil. The competition of the grass could be put an end to at once and the trees very much nourished by the use of an easily found mulching from materials which are often abundant in a country place. Among the best of these, where plentiful, is the common Furze, if cut down in spring and placed over the ground round the base of

young or poor orchard trees. It prevents the grass from robbing the trees and lets the water fall through to the ground, helping to keep it there, too, by preventing direct evaporation; moreover, the small leaves falling off nourish the ground. So again the sweepings of drives and of farm or garden yards are useful, and also any small faggots—often allowed to rot in the woods after the underwood is cleared. They fetch such a low price that they are not worth selling, but if placed round the roots of fruit trees they often do good. Then also there are the weeds and refuse of gardens of all kinds which form detestable rubbish heaps that would be much better abolished, and all cleanings from the garden placed directly over the roots of poor orchard trees. There is so often an orchard near the garden, that this would generally be a handy way of getting rid of green rubbish, and if spread for a few feet on all sides about a tree would not only keep the grass in check, but the decay of such spare stuff year by year would promote healthy growth and good crops.

Even rank weeds, which swarm about yards and shrubberies, would help, and one of the best ways to weaken them and help towards their destruction is by mowing them down in the pride of their growth in the middle of summer—nettles and docks, as the case may be—and instead of burning them or taking them to the rubbish heap, use them over the tree roots. Even the weeds and long grass growing round the base of the trees, if mown and left on the ground, will make a difference in the growth and health of fruit trees. Such care is all the more needed if our orchard is upon poor or shaly soils in the southern or home counties where the rainfall is less than in the western counties or in Ireland or Scotland: in naturally rich and deep soil we do not need it.

FENCING THE ORCHARD BEAUTIFUL.—All fences should be of living things at once the most enduring, effective, and in the end the best. We see the hideous result of the ironmonger's fence in marring the foregrounds of many landscape pictures. Holly, Quick, or Cockspur Thorn, with a sprinkling of Sloe or Bullace here and there, give us the best orchard fence; once well made, far easier to keep up than the iron fence. Yew is a danger, and a Yew hedge should never be planted where animals come near, as they usually do, the orchard, and if the Yew comes by itself, as it often will, it should be cut clean out and burnt as soon as cut down. Holly is the best evergreen orchard fence for our country, and we should be careful about getting the plants direct from a good nursery—clean seedling plants not much over a yard high. The best time to plant Hollies is in May if growing in the place, but on light soil plant in autumn; all the more need to do this if we bring the plants by rail. Unless the soil is very light I should plant on a bank, because a turf bank is itself such a good fence to begin with, and a free Holly hedge on a good bank, with, perhaps, a Sloe here and

there through it, is one of the prettiest sights of the land, and forms the best of shelters for an orchard in our country. Where shelter is much sought the hedge should not be clipped, and is much handsomer so grown. The orchard fence should not be cut in every year to a hard line, but Sloe, and May, and Sweet Brier, and wild Rose left to bloom and berry, the hedge to be a shelter as well as a fence, and not trimmed oftener than every ten years or so. Then it should be cut down and woven together in the strong way seen in parts of Kent on the hills.

VARIETIES OR KINDS TO PLANT.—The English fruit garden is often a museum of varieties, many of them worthless and not even known to its owner. This is wrong in the garden, and doubly so in the orchard, where the fruit trees should be trees in stature and none of poor quality. Too many varieties is partly the result of the seeking after new kinds in the nurseries. In orchard

fruit trees of Northern and Central Europe, and particularly Russia, would be well suited for our climate, but as yet little is known of these except that they are very interesting and many of them distinct. The vigour of the tree should be considered and its fertility. Kinds rarely fertile are not worth having, always bearing in mind, however, that a good kind is often spoiled by a bad stock or by conditions unsuited to it.

The beauty of flower of certain varieties may well influence in their choice. Once when talking with Mr. Ruskin of the beauty of the fruit as compared with the flower of our northern fruit trees he said: "Give me the flower and spare me the stomach-ache!" And many will sympathise with the view, which is also a consolation for the many who get no fruit from their trees.

THE ORCHARD WILD GARDEN.—One of the reasons for a good orchard from the point of view of all who care for beauty is its

sides of it Daffodils, Snowflakes, Snowdrops, wild Tulips, or any like bulbs to spare from the garden; and from the garden trimmings, too, tufts of Balm and Myrrh to live for ever among the grass of the bank. The robin would build in the Moss of the bank, the goldfinch in the silvery Lichen of the trees, and the thrush, near the winter's end, herald the buds with noble song.

STAKING ORCHARD TREES.—Fruit trees grown in any way are fair to see in the time of flower and fruit, but our beautiful orchard must be in turf if we are to have the best expression of its beauty. In fruit gardens where the whole surface is cultivated with small fruits below and taller trees overhead we may get as good, or, it may be, better, fruit, but we miss the finer light and shade and verdure of the orchard in turf, the pretty incidents of the ground, and the animal life among the trees in spring, as sheep in Kent, and the interest of the wild gardening in the grass. Also the orchard turf, by its shade or shelter, or in some way, becomes most welcome nibbling for lambs and calves in the spring. A gain of the orchard in turf is that we can put it on any ground, however, up a hill or down a dale, and in many parts of the country there is much ground of this sort to be planted. Now, while we may in the garden or the fruit garden plant trees without stakes, we cannot do so in the grass orchard, because of the continual incursions of animals; therefore staking is needed, not only to support the tall and strong young trees which we ought to plant, but also to guard against injuries by animals. The best way is to use very strong stakes and make them protect and support the trees and also carry the wire, which is essential wherever rabbits, hares, goats, or other browsing animals exist. The best way to do this is to have a very stout stake—Larch or old Oak. Sometimes in the *debris* of old sheds a number of rafters are turned out which are of no use for building, and are excellent for staking strong young trees in orchards, first digging the hole and putting the stake firmly in to a depth of 3 feet below the surface. Cradles of Oak and iron are much in use; the first is very well in an Oak country where labour is plentiful; iron is costly and ugly, and not so good as the single stout stake, which is easy to get of Larch or stub Oak in many country places. The common way of tying a faggot of sticks is not sufficient protection where animals have the run of the orchard. The trees should be tied with care with soft ropes of straw or other material, and when planted be loosely but carefully wired with netting well out of the reach of browsing animals. This wiring is supported well by the strong stake, and, well done, it keeps rabbits and hares, as well as cattle, at bay, and, worse than all for trees, young horses.—W. R.

Mr. S. W. Fitzherbert sends us the following description of a

DEVONSHIRE ORCHARD.

The lover of the beautiful in Nature who, at the season of Apple-blossom, has a little spare

An orchard near Glastonbury.

culture we should be chary of planting any new kind, and with the immense number of Apples grown in our own country already, it is always possible to select kinds of enduring fame, and it is the more necessary to do this now when good Apples are coming from America, where people do not plant a collection when they want a crop of a few first-rate kinds which they know will be precious in the market. So we should in our orchards never plant single trees, but always, if possible, having chosen a good kind, plant enough to make it worth gathering, noting and looking after it. It would be better here not to mention any particular kinds, because local kinds and local circumstances often deserve the first attention. Some local kinds of fruit are among the best. Any fruit requiring the protection of walls or in the least tender should never be put in the orchard. It is probable that some of the

value for wild gardening. It is so well fitted for this, that many times Narcissi and other bulbs from the garden have even established themselves in it, so that long years after the culture of flowers has been given up in the garden, owing to changes of fashion, people have been able in these orchards to find there naturalised some of the most beautiful kinds of Narcissi. Where the soil is cool and deep, these fine hardy bulbs are easily grown, and in warm soils many of our hardiest and most beautiful spring flowers might easily be naturalised. Those who care for beauty as much as fruit may throw careless garlands of the hardier Clematis, such as the Indian early and late-flowering Clematis, over the trees here and there. They do not rob the ground much and add a careless grace which is always welcome. On the cool side of the orchard bank Primrose and Oxlip would bloom long and well, and on all

time on his hands might do worse than spend a week amongst the orchard lands of South Devon, for it is not from the high roads, enchanting as are many of the views obtainable from them, that the sequestered valleys and secluded retreats, where rural loveliness reigns supreme, can be explored.

The old-time Devon orchards, though doubtless deserving but sparse commendation from an economic point of view, leave little to be desired in the way of picturesque effect. It may be said, with truth, that in the spring-tide of the year every orchard is a beautiful sight, but much depends upon the surroundings, and in this respect the orchards of Devon are highly favoured, for the conformation of the land is such as to augment their charms.

Down into the deep coombes dip the narrow, winding lanes, scarce wide enough to admit of two carts passing, except at the gateways. Here the banks are scarred with Primroses and Violets, and as one nears the lower levels, the sound of running water is borne upward from the brook that meanders through the old orchards—orchards where the gnarled and Lichen-covered trunks stretch away in gracious vistas—carpeted with the lush green of the grass and canopied with the shell-pink of the Apple blossom—blossom “as tender in colouring and delicate in fragrance as the rarest exotic.” No dream of poet or painter has ever evolved a vision more exquisite than these suavely-tinted blooms clustering so thickly on the spreading branches. It is here that Bacon’s words recur most insistently to the mind—“The breath of flowers is far sweeter in the air, where it comes and goes like the warbling of music, than in the hand.” One has no thought of cutting even a single spray, with its rosettes of blossom, crimson in the unopened bud, pink in the cupped blooms and white in the maturer petals, little though its product would be missed at the autumnal harvesting. It is enough to gaze and to appreciate. Here the sward is golden with countless Buttercups; here spangled with the softer tints of the Lent Lilies and with pale Lady’s Smocks, that congregate most numerous by the verge of the murmuring stream, where, later in the year, the Meadow Sweets will lift their ivory-white plumes and load the summer air with perfume. Here and there some venerable patriarch, with trunk inclining considerably out of the perpendicular, leans heavily on an outstretched, Moss-grown arm whose interlacing branches sweep the very grass with a cascade of flower. One or two of the oldest trees have succumbed entirely to the stress of some infrequent storm, probably the disastrous blizzard of 1891, which wrought such havoc in the west country, though it is rarely that the gales preserve the fury of their onslaught through the many windings of the valley, and lie with prone boles, over which in the early days of the year the young lambkins leap, half hidden amid strong-growing herbage. There is a hush beneath the Apple-boughs—a sense of peace and aloofness from the world, that is intensified by the intermittent melody of bird voices—the cuckoo’s call, the bird that has “no sorrow in her song, no winter in her year,” whose note seems from earliest childhood to have been the vocal expression of Apple-blossom, so intimately have the two been associated in our minds; short trills of song from the goldfinch, whose nest is aloft among the flower-laden branches; occasional notes from thrush and black-bird, reminiscences of the dawn-chorus in which, as day was breaking, they sustained the leading rôles; the woodpecker’s laugh, as with undulating flight and scarlet crest aglow

he seeks the hollow trunk in which the circular entrance to his nest has been so laboriously hewed; the faint note of chiff-chaff from the hedge where, on swaying shoots, the earliest Dog Roses are expanding their petals; and the harsh cry of the jay, whose azure wing-band glances momentarily into sight beneath the tree, the lowest fork of which holds his root-lined nest. Now and again a swallow skims—a blue-black flash—adown the blossom-roofed aisles, or a sulphur butterfly flutters lazily and indifferently to and fro over the sun-dappled grass, while in the air there is a drowsy hum of insect life, for the bees are busy on these bright mornings, possibly remembering the couplet, “a swarm of bees in May is worth a rick of hay.” One of these valley-orchards ascends the steep hillside almost to its crest, where with ruddy trunks and sombre foliage stand the tall Scotch Firs. Half-way up the slope one comes upon a spot where the face of the rock has been exposed, a disused quarry, over the verge of which hangs an Apple tree in full bloom, while a ruined shed hard by is smothered in the luxuriant growth of Ivy. From the high ground beneath the Firs the valley lies curving seawards, its prevailing tint being the pale pink of the Apple-blossom, though here and there a grass field alternates its restful colouring, or the red South Devon soil shows up, while a filmy thread of blue smoke floating skyward against the tender green of the Larches’ fresh leafage, one of the most delicate hues to be met with even in this spring world of clear colour, marks the site of some thatched cottage-homestead.

Strolling further down the lane one reaches more orchards, all delightfully picturesque, but each possessing its own individuality. In one, perhaps the most neglected of all, there are but few trees left, and those that remain are wreathed in Ivy and wild Clematis. The dew-sprinkled grass is thickly studded with the white star-flowers of the wild Garlic, beautiful indeed to look at, but emitting a most pungent smell when bruised. Here, in a deeper channel, the stream runs silently, but ever and anon a faint murmur is wafted up the valley, the distant voice of the heavy, overshot mill-wheel that ponderously revolves 100 yards below. Beyond the mill and the wheelwright’s roadside workshop, with its pent-house roof, the stream passes beneath a one-arched bridge, in the shadow of which the troutlets lie, and skirts yet another orchard, forming at one end a wide pool, around whose margin the house-martins are busily engaged in collecting mud for the building of their nests, while now and again a swallow with headlong sweep stirs with its wing the still surface of the pool into ever-widening rings that cause the reflections of the flower-clustered Apple boughs to waver tremulously in the watery mirror. Beautiful as are the orchards of this secluded valley, there lies another, at a distance of some miles, that might perhaps be considered even more favoured in its surroundings, since both land and sea combine to enhance its attractions. From the inland hills a short but steep-sided coombe runs downwards towards the shore, terminating at the water’s edge in abrupt cliffs some 40 feet in height, which on either side the cleft rise to a considerably loftier altitude. On the eastern ridge of the coombe a belt of Scotch Firs, beneath which stand large Horse Chestnuts, acts as a screen, while to the south-east a thick plantation between the orchard and the sea provides effectual shelter from the prevailing winds. In this sanctuary the Apple-blossom appears in the fairest setting, for here is the dark green of the Firs, the fresh emerald o

the great Chestnuts’ fan-leaves thickly set with white flower-spires, and, beyond, the sapphire of the sea, flecked here and there with brown-sailed fishing-boats, white-winged yachts, and on the far horizon the tall top-sails of some homeward-bound barque or lofty spars and dim smoke-trail of hull-down Atlantic liner.

Many a delightful picture is presented by these informal orchards—beautiful, differing merely in details of environment and accessories, and, though it must be admitted that it is at blossom-time, when the year is young, that they attain the zenith of their loveliness, yet what is more typical of autumnal affluence than the loaded branches bending beneath the weight of rosy fruit, when the yellow stubbles stand bare of the reaped corn, and what colour-scheme can the dark November days provide more brilliant than the wide-based pyramids of Apples glowing on the emerald-green of the grass with their mingled hues of crimson, orange, and saffron!

STOVE AND GREENHOUSE.

WINTER-FLOWERING CARNATIONS.

THERE is no lack of beautiful subjects to follow the Chrysanthemums, but in many places the number of these that are grown is altogether out of proportion to the house room, and other things have to be neglected to make way for them. Plants that can be grown on outside or in frames during the summer and housed in late autumn after the crops are removed from Melon and Cucumber houses are useful, and among these the winter-flowering Carnations stand high. There is not of course the beauty of colouring that we see later on in the summer-flowering border varieties, but their present popularity and the number of new and lovely kinds constantly appearing show they have obtained a hold. Their culture is not difficult, but constant care from the time the cuttings are inserted until the plants are in flower is required. The cuttings consist of the small stubby side shoots that are more or less freely produced according to the variety. It is difficult to get enough to perpetuate some kinds, while others produce abundance. To ensure rapid rooting and prevent damping, the earliest batches at least should be given a gentle bottom-heat with a rather close atmosphere overhead, such as is provided in propagating cases and the like. This being very liable to bring insects in its train, the cuttings ought first to be dipped in a fairly strong solution of tobacco juice, and before the case is filled, this and the glass must be thoroughly cleaned. A little clean cocoa-nut fibre or tan may be used to plunge the pots in: these may be 4 inches wide and contain three or four cuttings, using a light sandy compost. It is important that the warmth be kept steady, and as soon as the cuttings are rooted, take them out and stand in a similar temperature without the bottom-heat for a few days. Gradually admit a little more air to slightly harden them before potting the young plants singly, this taking place before the roots are too far advanced. Pot at first into 3-inch pots, and see that these are thoroughly cleaned. A couple of large pieces and a few small crocks, with a little rough peat fibre over, make an excellent drainage, the compost consisting of light turfy loam three parts, one part of half-decayed leaf-soil or peat and decayed cow manure. As the pots are small, this must be used in a rather fine condition, but when re-potting again becomes necessary, the same

material used in a rougher state will do well. In potting into the small size, just press the soil into position with the thumbs and a gentle tap on the potting bench. If this repotting can be carried out in the house where the plants have been growing it is all the better, as the cold air coming into contact with them at this early season is not advisable and often leads to an attack of aphid, the worst insect enemy. When again established, begin to harden the plants a little preparatory to their removal to a light, well-glazed pit, when if necessary a little warmth may be turned on. By this time the season will be advancing and the sun gaining power, so heat will be very seldom needed.

It is now that the greatest care is necessary. The plants have to be inured to the altered conditions, yet no check must be given, and careful ventilation of the pit must be practised. Should there be the least sign of greenfly—and fortunate indeed will the grower be if this insect does not appear—the pit must be gently fumigated two or three nights in succession. If kept clean and not checked, the little plants will soon take on quite a robust look, and then they are sure to do well with ordinary precautions. No stated time can be given for the next shift, as, no matter how carefully they are grown, they will not all be ready at once; nor is it advisable to pot them all at once, as a longer succession of bloom is kept up when they are placed into the flowering pots at intervals. It is no use repotting until there are roots enough showing on the outside of the compost—when turned out for examination—to ensure their taking a good hold of the new compost. Pot rather firmly this time, as this conduces to a solid rather than a rapid growth, and once again established the plants may have full exposure by day, except in heavy rains, and a liberal amount of air left on at night. Watering from the first is an important item, and more plants are killed by injudicious use of water than by any other mistake in culture. There are many good fertilisers now advertised, and any of these, if used with proper caution, is very beneficial after the pots are thoroughly well filled with roots. As soon as the houses can be spared in autumn, the plants may go inside, the stages, roof, and walks having been first thoroughly cleaned. Light span-roofed structures are best for them, and these, as long as there is no danger from frost, may be left quite open by day and night. From this time onwards a minimum temperature of 50° and a maximum of 60° is ample, and if the house remains at this there is no need of fire-heat, excepting in wet weather to dispel superabundant moisture. Frequent and light fumigations will be necessary right on until the flowers commence to open. A little thinning of the flowers will be necessary, and if grown specially for cutting, the sooner they are removed after fully expanded the better. These few details carefully carried out will enable anyone to grow these beautiful flowers and keep up a good succession over several of the duldest months in the year. GROWER.

Varieties of Impatiens Sultani.—This Impatiens, which was so popular some sixteen or seventeen years ago, still remains a general favourite, and deservedly so, for its brightly-coloured blossoms may be had more or less continuously throughout the year. Besides the ordinary form there are some distinct varieties, and a charming feature they make just now in the stove. One of these—*carminea*—has blossoms of a bright carmine-red shade, while the distinct salmon hue of *salmonea* is very pleasing. There is also a variety with variegated foliage, but it is

seldom satisfactory. These forms of Impatiens are so readily propagated by means of cuttings and of such easy culture, that no fear need be entertained as to their success. There are many other desirable stove species of Balsam, but they do not contain such an every-day plant as *I. Sultani*. The brilliantly coloured *I. Hawkeri* is occasionally seen in good condition, but not often, while *I. Hookeriana*, a native of Ceylon, that usually blooms about midwinter, would doubtless be much more extensively grown but for the fact that it seldom flowers in a satisfactory manner. In this the large white flowers are marked on the lower portion with blood-red streaks—a startling contrast. *Impatiens auricoma*, which was introduced and much talked about a few years ago, appears to be of little value.—T.

DIEFFENBACHIAS.

Among stove plants with variegated foliage these form a distinct contrast to most other subjects, and although not quite so useful as many others, a few of the best sorts should be grown, for in addition to being very distinct, they are most effective when well grown. It is only when grown on freely from young stock that they are seen at their best. After plants get a certain age they deteriorate, the foliage being smaller and the plants leggy and unsightly. There is little difficulty in propagating. The tops will usually root if taken off to where the stem is fairly firm. They are inclined to bleed, but to stop this they may be put in quite dry sand and left for a short time, and after putting them into pots they should not have sufficient water to penetrate to the base of the cuttings for a day or so, giving only a slight sprinkling overhead and keeping close in the propagating pit. Very strong cuttings are apt to rot at the base, but if the tops do fail the old stems will give a lot of young stock, either kept in the pots and the tops taken off as they are ready, or they may be shaken out and the stems laid down in cocoa-nut fibre refuse or other suitable material. If the stems are firm they may be cut into short lengths, but if soft and fleshy they are liable to rot. It is not necessary to put them into the close pit; any warm place will do. As soon as young plants are established they should be potted in a compost of loam, leaf-mould, peat, with some manure and plenty of sand. After they have made a good start, liquid manure may be used freely. They like plenty of moisture at the root. In a moist atmosphere they may be grown fully exposed to the sun throughout the summer.

Of varieties, *Bausei* is one of the most popular. It is very distinct, and makes a well furnished plant. *Magnifica*, with large deep green leaves, distinctly blotched with white, is one of the most robust. *Regina* has deep olive-green leaves with yellowish blotches, and *Jenmanni* has narrow leaves with white markings. *Shuttleworthi* has pale green leaves with a grey feather-like marking radiating from the midrib. *D. eburnea* is another distinct variety with narrow leaves, spotted with white, and a reddish brown leaf-stalk. There are no doubt others equally worthy of culture, but the above are a selection I made some years ago, and have found them very serviceable. If propagated periodically and well treated, there is little difficulty in having dwarf, well-furnished plants with large well-marked foliage. The juice is very poisonous, and care should be taken when using the knife not to allow it to touch any cuts or sores. II.

Begonia Dregei.—That extremely popular variety of *Begonia*, *Gloire de Lorraine*, was shown by several different exhibitors at the Aquarium on December 6. In Mr. Cannell's group there were two or three plants of *Begonia Dregei*, which is one of the parents of *Gloire de Lorraine* (*B. soeotrana* being the other), and the little white blossoms of the older species, combined with the profusion in which they are borne, afforded a pleasing variety to the masses of rich pink furnished by the other. *B. Dregei* forms a

stout fleshy root-stock, from whence are pushed up stems of a succulent character that reach a height of 18 inches or thereabouts. The leaves are rather small, thin in texture, and freckled irregularly with grey, while the small white flowers are very numerous. It is a native of the Cape of Good Hope, from whence it was introduced in 1840. If taken in hand and grown as Mr. May, of Edmonton, grows *Gloire de Lorraine*, this original species would doubtless attract a good deal of attention. Apart from its own intrinsic value, *B. Dregei* has proved of considerable service to the hybridist, as besides the part it played in the production of *Gloire de Lorraine* (above alluded to), it was in conjunction with *B. Sutherlandi* employed by the late Colonel Trevor Clarke, the result being *B. weltoniensis*, which was raised about thirty years ago and for a long time was very popular.—H. P.

ROSE GARDEN.

INDOOR ROSES.

FORCING Roses very early in the season requires a lot of care and skill, specially prepared plants and constant watchfulness more than the average busy gardener can give. It is, in fact, almost a speciality of the market men who cater for the demand through the earliest months of the year. But to bring Roses on gently so that abundance of bloom can be produced long before the outdoor flowers appear is not difficult, and the veriest tyro in gardening may take this mode up with every prospect of success. There is no difficulty in getting a supply of flower from the end of March onwards either in houses where the plants are brought in from the open or in a Rose house proper, where *Maréchal Niel* or some other climbing kind is thinly trained over part of the roof and the beds or borders inside the house filled with different kinds of Teas and Hybrid Perpetuals. In making a Rose border it is much better to do the work thoroughly at first, though there are many places where a good natural soil exists and little trouble is needed. But because Roses thrive well in the open it does not always follow that the soil will be good enough without any other aid when it comes to growth indoors. In the first place, the fact of its being under glass prevents natural fertility to some extent; again, the plants will probably have to stand more thickly on the ground, and Roses under glass flower over a longer season and make more wood than they do outside. Whenever there is any doubt then as to the soil where Roses are to be planted, let suitable additions be made to it. If heavy and unworkable, add burnt earth and light sharp material, such as road-sand. If light and very sandy, marl or even clay may be added and cow manure partly decayed. When dealing with a light sandy soil in Gloucestershire I had splendid results with all the Tea-scented kinds by using the decayed cow manure.

Respecting the choice of plants for growing inside, they should be worked on the Brier cutting or else be on their own roots. With many of the stronger-growing kinds there is no difficulty in striking and growing them from cuttings. Indeed, I have yet to see the variety that will not eventually thrive in this way under glass at any rate, though the progress at first may be slow. Plants of Hybrid Perpetuals may do so on the *Manetti* stock, but Teas are not satisfactory, while as for the *De la Grifferaie*, it is absolutely worthless for all but the strongest growers. It makes a pretty hedge if allowed to run wild, but I shall never use it again for budding Roses on. Grafting on seedling or Brier cuttings is a better way than this, for

when such plants are put out with the point of union below the soil, they are sure, in the majority of instances, to eventually root from the scion. I would like, however, to point out that this is not always as advantageous as some growers think. It is a slight help certainly, but I have pulled up scores of plants that had rooted in this way, and those with strong roots from above the top of the stock were very much in the minority. With regard to

PRUNING.

not much need be said. In the case of Hybrid Perpetuals, the demand for long stems does away with the necessity for much of this, and little growth remains in many cases after the flowers are cut. It is a weakening practice for the trees, but it shows taste on the part of the decorator. The pruning of the Tea-scented kinds is simple. Cut out what is old and worn out and whatever cannot be found room for; run up plenty of long vigorous shoots on *Maréchal Niel*, *Bouquet d'Or*, *Gloire Lyonnaise*, and others of this class, and cut them out entirely after flowering, much finer blooms that may be cut with longer stems resulting from this mode than from that which necessitates the leaving of a lot of small spray and old wood in the plants. Early in the new year the house should be closed and fumigated two or three nights in succession, the plants having previously been cleaned and put in order. Proceed slowly, will be a good maxim as regards the rise of temperature, but a house once started and the buds on the move, the trees must never be checked by a fall in the temperature. Start with a night temperature of 40°, rising by slow degrees till 55° is reached, and endeavour to increase the temperature almost imperceptibly, as it were. In the earlier stages many plants have the growth softened, and therefore weakened, by syringing—a useful aid to culture if judiciously practised, but leading to a good deal of trouble if gone about carelessly. As long as the temperature will allow of a little air being left on the ridge of the house at night, afternoon damping may be practised, and on bright, mild mornings the syringe may be freely plied about the stems, making any chance insects uncomfortable and serving to keep the foliage fresh. Avoid cold draughts of air, mildew following with certainty any neglect of this rule. In fact, this pest is almost sure to appear sooner or later, and the grower must be prepared with remedies at once. Sulphur dusted over the first mildewed leaves keeps it in check, and occasional syringing with clear soot water is an excellent preventive. As the flowers advance the sun gets more power, and to prevent the buds of *Isabella Sprunt*, *Mme. Guinoisseau* and others of these delicate and beautiful kinds opening too quickly, a light shade may be necessary. When wanted for a certain date, and it is evident they are too forward, they may be retarded a few days at least by placing a little oiled paper around them, leaving the top open and tying loosely at the stem. After the first flush of bloom is over and the house is thrown open for the summer, an immense number of small, but beautiful buds will be produced even until quite late in the season where these delightful Teas are grown.—A GROWER.

— To force Roses successfully in any quantity a separate house is necessary, as unless their every want is attended to failure will occur. Market growers who force Roses by the hundred or thousand usually stand the plants on benches covered with rough ashes in span-roofed structures, and find it answer well. For my own part, where only a limited number of plants is grown for home decoration, I prefer giving the

roots the benefit of a gentle bottom heat. This to some may sound superfluous, but I have proved its value, and if a small, lean-to house, having a pit which can be filled with leaves, is at command, nothing answers better. The price being now so reasonable, these forming or renewing a small collection cannot do better than purchase strong, well-ripened plants in 6 inch pots, and for a supply of bloom in March introduce them into the forcing house at Christmas. The pit being filled with leaves, the plants, duly pruned and drainage examined, should be stood on the surface of the bed for a start. Very little water will be needed till growth is on the move, when the pots should be half plunged and allowed to remain at that. No air should be given during December and January, as this often produces mildew. The leaves supply ammonia, which helps to ward off insects and also assists growth. When growth

leaf-mould may form a fifth part of the compost.—B. S. N.

GARDEN FLORA.

PLATE 1203.

FUCHSIAS.

(WITH A COLOURED PLATE OF *F. MONARCH*.)

HYBRID Fuchsias appear to have been first raised about the year 1837, and since that time every year new varieties have been added and some great improvements made, yet the achievements of the earlier hybridisers seem difficult to beat, especially for habit of growth and abundance of bloom. I cannot give the date of the introduction of *Rose of Castile*, but

Fuchsia General Roberts.

becomes active and new roots are numerous, weak liquid manure may be given at each watering, and during February the foliage should be syringed on fine sunny days. For the first three weeks or a month a maximum night temperature of 45° should be aimed at, raising it to 50° when the new shoots are a few inches long. As the season advances a liberal supply of air must be given and several moderate fumigations with tobacco before the first blooms open. Flowering over, all the air possible must be given before placing them in cool summer quarters. For the first three weeks the plants should have the protection of canvas fixed over a temporary framework of wood. At the end of August or beginning of September any needling it should be repotted, and the rest surfaced with good holding loam, bone-meal, and coarse sand. In the case of Teas,

I have known it upwards of thirty years, and it still remains a favourite with many. Smith's *Avalanche*, which came out about that time, is another which is extensively grown for market at the present day. I find both of these varieties received first-class certificates in the year 1872, at which time the Fuchsias seem to have been most popular, for out of about seventy awards made by the Royal Horticultural Society, twenty were gained during that year. The advent of the tuberous *Begonias* somewhat diverted the attention of growers from Fuchsias, yet I believe they are coming into popular

* Drawn for THE GARDEN in the Royal Gardens, Kew, by H. G. Moon. Lithographed and printed by J. L. Goffart.

favour again, and deservedly so, for no other class of plants keeps up a more continuous succession of bloom, and from plants a few months old up to large specimens, Fuchsias are equally beautiful. The largest specimens I have seen were some exhibited in Brighton—the first flower show I ever attended. The same plants did service for a number of years, and among the sorts were included Sir Colin Campbell, with a large double purple corolla and red tube and sepals; Mme. Cornelissen, with double white corolla, and Rose of Castile. These plants must have been several years old, for they had hard wood to the height of about 5 feet, and all the lower branches were of matured wood, being pruned annually into shape in somewhat the same way as a pyramid Pear tree.

Quite large plants may be had in one season if the cuttings are put in early and proper attention paid to potting on as they require it. I prefer these to the old pruned-back plants, as they make finer foliage and larger flowers. There are several sorts which may be grown on from cuttings without any stopping and that will branch out and make symmetrical pyramids. To do this they must be strong cuttings to start with and must have attention, giving them plenty of room. Where it is desired to grow a few extra large specimens, they should be stood out singly or elevated on inverted pots, taking care that the lower branches are not shaded in any way. Fuchsias may be grown fully exposed to the sun provided they are not allowed to suffer from want of water. When in full bloom a slight shading will be advisable in very bright weather, as the flowers will hold on longer. Among recent additions are those with the long tubes and sepals. Earl Beaconsfield was one of the first of this class, and many others have been added since. They are not so compact in habit as the varieties grown for market, but they make fine specimens. They are also well suited for training to pillars or for the roof of a conservatory. Monarch (which is well shown in the coloured plate) is a good example of this class. Other good varieties for pillars or roofs are Olympia, salmon-pink tube and sepals, red corolla; The Shah, bright scarlet tube and sepals, and deep blue corolla; General Grenfell, coral-red tube and sepals, and bluish purple corolla; Mrs. Rundle, pale flesh tube and sepals, salmon-shaded corolla; and Mrs. Tadman, white tube and sepals, with a

tint of pink, scarlet corolla. During the past season I saw these varieties in fine condition at Messrs. Veitch and Sons' Chelsea nursery, where they were trained to the roof of a span-roofed house and were most effective. Of varieties with double corollas, Phenomenal, of which there are three varieties—one with a purple, one with a pink, and another with a white corolla—is the largest. These do not make such compact plants, but the flowers are remarkable for their size. Alfred Rainband, Mme. Carnot, and Duc d'Aumale are other newer sorts well worth growing. In growing

FUCHSIAS FOR MARKET,

the first thing is to see that the stock

Fuchsia Queen of England.

is quite free from all insect pests. Of course this also applies to plants grown in private gardens. By keeping only a limited number of plants and giving them proper attention, more and better cuttings will be obtained than where a larger stock is kept in an unsuitable position. Before starting the stock plants into growth they should be thoroughly fumigated or dipped. The insecticide may be used much stronger before there are any young leaves, and thus ensure destroying any spider or other insects that may be on the stems. I like to have the plants in a

moderate temperature and fully exposed to the light. This ensures strong, short-jointed cuttings, which are of the first importance, especially for those grown on without any stopping. Most market growers use the shallow boxes for cuttings, and place them on a stage where there is a good heat beneath. If kept fairly moist they require little shading, will root as freely as if placed in a close pit, and are not so likely to get drawn. If potted as soon as well rooted and well attended to, they will soon be ready for potting on into the flowering pots, that is, 5-inch pots (the usual market size). After they have their final shift and are well rooted round the pots, manure may be used, beginning by using it weak and gradually increasing the strength. Either liquid manure or any of the artificial fertilisers may be used, but where the latter are given the foliage is more liable to get burnt by the sun if the plants are allowed to get a little too dry. It is surprising what large plants may be grown in the ordinary 4½-inch pots. Of course, after they are well finished and put on the market they do not last so long as when grown in larger pots and kept in the house where they have been grown. Yet being grown fully exposed to the sun they last longer than might be expected, provided they are not allowed to get too dry. It is only a limited number of varieties which find favour with market growers, and these include some very old sorts, habit of growth and freedom of flowering being considered before size of bloom. Rose of Castile is still grown. Arabella, or Mrs. Marshall, and Lady Heytesbury are the best of the light varieties. Secrecy is one of the best single dark reds. Avalanche is grown extensively. Another very fine dark kind with double corolla is Royal Purple. Ballet Girl has the finest double white corolla. Another new variety of merit is Tribute, with dark crimson tube and sepals and deep purple corolla.—A. H.

— Fuchsias are neither so generally nor so well grown for exhibition as they used to be, and few now care to keep the plants more than a few years. Plants two and three years old are the most serviceable, so that it pays to propagate a few each year. Young growths, shaded from bright sun, strike readily in a comfortable temperature; and where only a few are required, it is best to place one cutting in the centre of a very small pot; root-disturbance, by separating one from another, is then avoided at potting-off time and the young plants go right ahead. Fuchsias like a little warmth early in the year, say 50° at night, and should be syringed freely in fine weather to keep thrips away. This pest is liable to be troublesome in a dry atmosphere, and if once established must be destroyed by fumigation. A good yellow loam, with the addition of well-rotted cow manure and some coarse sand or road grit, will grow them well, and good drainage should be given. Young plants, if stopped when 6 inches high, will produce side growths. These may again be stopped, and good bushy plants in 6-inch pots secured by autumn. These will make grand bushes the following year. Fuchsias are often wintered badly, the common practice of storing them under stages and drying them off as one would a bulb resulting in many dead plants. The best position when at rest is a cool house, letting the plants remain in a natural position, so that a little water may be given occasionally to keep the wood sound and plump. Prune them well in in February or March and give a warm, moist house until May, when ordinary greenhouse quarters will be best. Liquid manure made from sheep or deer's droppings suits them well.—J. C.

THE WEEK'S WORK.

KITCHEN GARDEN.

GENERAL WORK.—Up to the close of the year the weather has been so mild that all work in the open should have been gone on with, and though heavy rains will have prevented wheeling or carting on to heavy soil during the last week, the land dried up quickly and the work may be proceeded with. Owing to the mildness of the season the weeds have never ceased growing, and hoeing between small crops is a necessity. If Lettuces and other small plants in seed beds are left alone the weeds will soon spoil the seedlings. Peas in the open sown at the end of November will now need soil drawn up to protect from cutting winds. I find it well to place small pieces of evergreens along the sides of the rows to protect the growth. Peas sown in pots in frames should be kept as sturdy as possible from the start, and if at all crowded it will be well to thin at this stage. The vegetables needed to keep up the supply for forcing should be lifted from their growing quarters and laid in soil ready for use, as with severe weather it is difficult to lift them. Artichokes should be dug up and placed in a clamp. Treated thus they keep sound, but if placed in a store they dry up and lose flavour. All vacant land should be prepared for future crops, and any standing crop should be cleared of decaying foliage and made tidy.

PROTECTING VEGETABLES.—There will now be more demand for tender vegetables than can be supplied from the open unless some means is taken to eke out the supply. Brussels Sprouts and early Broccoli are not nearly so plentiful as usual, this being the result of the dry weather in the planting season. Broccoli will lift well and give heads just the size needed if taken up before severe frost checks growth. It is not safe after this date to rely upon tying up the leaves over the flower. It is better to house the plants. The Cardoons this year made a much later growth than usual, but it will now be well to lift them and place them under cover. They will remain good a long time in a cool store. Good use may now be made of the large Batavian Endive as a vegetable if there are plants fully grown and not room to house the same. Chicory forced in the same way as Seakale, if grown slowly and the growths cut when 4 inches to 6 inches long, makes a good vegetable and an agreeable change. Vegetables stored some weeks ago must be kept as cool as possible. I notice Potatoes are growing out badly, and it should be borne in mind all roots that grow freely in the store will soon lose quality.

SOWING VEGETABLE SEEDS.—Cauliflowers sown on a gentle hot-bed will give a supply if the autumn-sown plants fail. I find it well to make up a bed of leaves at this date for sowing early in the year. Many need early Brussels Sprouts, and it is a gain to grow such, as in a very hot summer the smaller plants put out late make slow progress. My best sprouts this year were those sown last January. Of course very little warmth is needed and avoid thick sowing, as the seedlings damp if too far from the glass. I find a small sowing of an early kind of Lettuce most valuable, as this gives cutting material weeks in advance of that sown in the open, and forms a succession to the autumn-sown. The same remarks apply to Leeks and Onions, which well repay being sown under glass if size is needed. A small sowing of summer Cabbage will be useful if the spring crop is none too plentiful. Those who have cold frames may utilise them for present sowing.

SELECTION OF SEEDS.—The advice to sow a few seeds to furnish earlier supplies will bring to mind the necessity of selection for next season's supply. I strongly urge growers who may not have had much experience to sow new seed of such vegetables as are a long time in germinating; for instance, Peas, as they are stronger and give a quicker return. Of course in many cases new seeds—I mean of this season's growth—are not a necessity. Any fleshy seed is best for later sowing, with more warmth in the soil to assist ger-

mination. As regards novelties, my advice is, try those the grower may think would be any improvement or add to the supply. Of late years we have had some very excellent additions to Peas, Tomatoes and other things, and if these had never been given a trial we should not have known their value. I fear seeds of certain vegetables will be scarce this year. Owing to last season's heat and drought, growth was poor and the yield small in consequence.

POTATOES.—Those who need frame Potatoes would do well to prepare the same by sprouting. Though I am aware it is not well to get the growths too much advanced previous to planting, a little growth is advantageous. In using composts for early Potatoes, it is well to use old soil or soil enriched with leaf soil, spent Mushroom manure, or burnt refuse, as in fresh, heavy soil the plants do not always tuber freely. The seed store may now be gone over and the sets prepared for planting by placing them in shallow boxes. It is a good plan to remove the weaker eyes from the sets, only leaving two strong ones; indeed, many good cultivators only leave one when it is seen which will take the lead. If the boxes when filled with the seed can be placed so that the air can circulate freely through them the new growths will be stouter. It is always advantageous to get seed from a different soil, and by doing so greater vigour is secured. There is no lack of variety, but Windsor Castle comes so good in all soils, that it should be grown in all gardens where quality is studied. Those who have not yet grown Ninetyfold will find this a splendid acquisition to the early kinds, and, in addition to its earliness, it is a splendid cropper. Many persons can grow early and second early kinds who have no room for late ones.

EARLY TOMATOES.—For many seasons I have devoted more attention to early Tomatoes, and at the close of the year the cultivator must begin to prepare plants for early fruiting. Those who may have rooted cuttings in small pots may now give a shift, and at this season of the year a better soil may be used to encourage rapid growth. It frequently happens that the plants after October get somewhat drawn, and to secure a dwarfier plant it will be well at potting to bend the stem round near the surface soil. The stem will soon root into the new compost, so that a dwarfier plant is secured. Of course, the burying of the stem needs care, but with a little more warmth after repotting, growth is soon active and a dwarf plant is obtained. I plant out the seedlings raised in August the first week in the new year. These I prefer to those raised from cuttings, as they are dwarfier and stronger. The temperature for the plants may now range from 55° to 60° at night, with a free rise by day, giving ample ventilation in bright weather, with a little on the back ventilators at night in mild weather. Plants raised now will fruit freely early in May. The seed should be given a brisk bottom-heat till germinated, and liberal treatment as regards warmth and light will be necessary from the start. Small plants raised late in the autumn should now get a shift and be given the temperature noted above for larger plants.

SALADS.—The weather up to time of writing has been so mild, that Lettuce has remained good in the open if not fully grown or blanched. Lifting of any plants large enough for present use should be no longer delayed. Nothing is better than frames if these can be spared, as the plants can be given more ventilation. If Lettuces are scarce, it will be advisable to make a sowing of the Golden Queen, a very quick grower. If sown in a frame it may be had large enough for use in April. There is no lack of good Endive, both Curled and Broad-leaved; the latter is the better keeper and should be kept as late as possible, as this is invaluable when Lettuces are scarce. Chicory forced is now valuable, and may be grown in larger quantities in midwinter to eke out the Lettuce supply. The smaller salads, such as Mustard and Cress, I sow in boxes every ten days, placing on warm pipes, the seed being

covered with brown paper. Cress often damps or mildews if covered too deeply or given much moisture; indeed, it is best covered as advised till the seed has germinated.

HERBS.—There is always a demand for green Mint early in the year, and a portion may be lifted now and either placed in boxes or on the floor of a warm house. I prefer boxes for a very early supply, as if needed quickly it is an easy matter to hasten growth. Much better results follow forcing strong roots, and these I obtain from cuttings struck in May or early June, the strong growths being selected from 4 inches to 6 inches in length. These grown on for two seasons in rich soil make splendid forcing material, being quite different from weak, thickly-matted, old roots. If large quantities are needed, the roots do well placed on the floor of a fruit house, as if not shaded in any way they will start quickly and the crop be cleared by the time the trees are in leaf. Tarragon is a favourite herb in a young green state. This can be forced as easily as Mint, and in many places the green Basil is preferred to the dried, so that seed may be sown in boxes for an early spring supply. The herb borders may get a covering of light manure to the depth of 3 inches. This will protect and give earlier supplies from the open ground, at the same time enriching the roots. Parsley so far has stood well, but some may be protected in case of severe weather. Young seedling plants may with advantage get a dressing of soot, soil, and bone-meal to encourage growth for summer supplies. S. M.

FRUITS UNDER GLASS.

PINES.—The stock of The Queen, which was rested early with the view of starting the plants in good time, may now be gone over, being examined and rearranged so as to commence with the new year in order to have ripe fruits at the end of May or early in June. If the bottom-heat material was not put in order in the autumn, as suggested when a thorough clearance was advised, it should now be done. Leaves and a small proportion of horse droppings that are moderately fresh will make a good plunging medium. I prefer it, all things considered, to tan, which is, I am quite aware, very good for the purpose, but the troublesome and oft-repeated growth of a fungoid character, which one would imagine could not exist after the process it (the tan) had gone through, has to be encountered. Even if tan be used to some extent I would still prefer to have the bottom part of leaves, or leaves and manure, pressed down firmly. For a few weeks there will not be any necessity to apply bottom-heat by means of the pipes fixed for that purpose. With a bottom-heat thermometer it will be easy to note the warmth in the beds. It should not rise beyond 80° for a few weeks, whilst the night temperature should not exceed 65° nor that of the day more than 75°. When rearranged a good soaking of warm water should be given the plants, say at about 80°, nothing but clear water being used at first or until growth is active with the fruits showing. Remove any suckers which perchance may have escaped notice in the autumn or have been too small then to claim attention. A light top-dressing of turfy loam and peat pressed down firmly, especially around the stems, will be found by the roots before long. Guard against any drip in the hearts of the plants, as it will at times lead to malformed fruits in their earliest stages. Let the evaporating troughs be kept filled, with a moderate damping down of the pathways and walls as well as upon the surface between each plant. Rather than fire excessively hard, a slight drop in the night temperature is recommended when they cannot be maintained without covering up. This should only be resorted to in very cold weather or when a keen wind is blowing. Should planting out be in vogue, let the border be first well pressed down, mulched as advised for pot plants, and then be watered. A few of the winter stock may still be in hand, yet not sufficient to keep one com-

partment occupied in a profitable manner. These if possible should be placed by themselves, but still maintaining the temperatures, where they will not occupy so much space. This will afford the means of preparing for another stock of fruiting Queens or of suckers which it is desirable to push on early in the new year. Do not, however, for the present entertain any ideas of repotting. If suckers from plants just fruited are kept, let them be put into small pots for the time being. Possibly such as these could be placed with the early Queens. If the stock of any kind is scarce it will pay to keep the old stools for future suckers. Keep a constant and sharp watch against the least possible appearance of white scale, which is more to be dreaded by Pine growers than all other insects put together.

MELONS.—FIRST EARLY.—Where Melons are looked for towards the end of April or early in May a start should now be made. Do not depend so much upon mere size for first early fruits as upon smaller and prolific free-growing kinds. As examples, Syon Perfection, Sutton's Scarlet, and The Countess are quoted. At this season of the year, with no prospect for another month of any really marked increase of daylight, it is not so easy a matter to raise young plants of good sturdy growth. They should be raised in such places as propagating pits where it is possible to keep them near the glass. The time-honoured plan of placing the pots with two seeds in each in the evaporating troughs is not at all a bad one when each pot is plunged to the rim in fibre. If the seeds lie long in the ground they are liable either to decay or to start weakly. A second sowing should follow within a week in case of any mishap. Better do this than sow so many all at once.

VINES IN POTS.—These, which were started early in November, are now pushing away freely, but, as usual, the uppermost parts of the canes were gaining in strength at the expense of the lower portions; therefore the former have been bent down for a time to regulate the flow of sap. With the plunging material of leaves only a warmth of 75° is maintained at the roots. This, with a night temperature of nearly 60° or thereabouts, will soon hasten matters, the moisture in the leaves lending a timely aid. Until root-action is free, watering will be attended to with some caution. A word of caution may be necessary as to the treatment of later pot Vines not yet started, and also of those which it is intended to grow on or those which are for planting out: this caution refers to the protection of the roots during frost. If the pots are not yet covered, if out of doors still, no time should be lost in doing so. I can very well remember a marked failure of pot Vines occurring which could not to all appearance be traced to any other cause. The pots so soon become cold, and as the chief part of the fibrous roots is around the sides they receive a check not so readily overcome as some would imagine. If these Vines be under glass, they are, of course, safe where frost is excluded, but in that case see that they do not get too very dry at the roots. The pruning of all of these Vines should now be done, dressing the wounds with styptic to prevent bleeding.

PERMANENT LATE VINES AND YOUNG VINES IN BORDERS, &c.—These should now be all pruned so as to give work in cleaning if bad weather supervenes, as well as for the good of the Vines themselves. These will all be safer if dressed with styptic or painter's knotting, which is equally effective. When late Vines are retarded during March there is often an inclination to bleed if the Vines be vigorous, and the same applies to young Vines in their exuberance of growth when the leaf development is not fast enough for them. See that all inside borders where the Grapes have hung up to Christmas are well watered at once. It is assumed that all late Grapes are now out, or will be within a few days' time. To let them hang later than this where there is a good Grape room is not expedient. I know it is done in large trade-growing establishments, but it taxes the Vines even when the buds are all cut

out back to the base buds and the roofs darkened by means of clay and lime. This treatment in private gardens cannot be recommended for general adoption, being most unsightly. Give close attention now to the bunches of Grapes that are out and placed in water in the fruit or Grape room; a night temperature of 45° as the lowest and 50° as the highest will answer well, with but little variation during the day from these figures. Remove every berry showing symptoms of decay, and take care to keep all the ventilators closed during frost, fog, and damp weather. See also that all young Vines where planted inside do not suffer from drought at the roots; when they do, it is simply ruinous to them. A case of failure now comes back to the memory, which was no doubt traceable to this omission to keep the inside borders well watered. When the cleaning of the Vines and the houses too is all completed give the borders a top-dressing or mulching. If it be a top-dressing, remove first the surface soil down to the roots in a careful manner and then add fresh turfy loam with some bone-meal or its equivalent. If this be done one year, the mulching alone another year will be sufficient; this may take the form of well-rotted cow or farmyard manure which is not too highly charged with ammonia. Where very early forcing of permanent Vines is not practised, the present is a very good time to start a house in order to have ripe fruit towards the end of June. If such a house has an outside border, guard against its being frozen, dry litter being a good covering medium. In no case should the Vines be left without a little protection at the roots during a sharp frost just around the stem where most exposed.

HORTUS.

CHRYSANTHEMUMS.

BORDER CHRYSANTHEMUMS AT CHISWICK.

A GREAT deal has been said concerning the above trial of Chrysanthemums, which were planted expressly for test purposes on May 26, 1897. To make that trial more generally complete, and, at the same time, serviceable, the plants were allowed to remain during the winter of 1897-8. The trial during the season of 1897 was satisfactory from all points, the plants almost without exception producing a wondrous harvest of bloom. So far, however, only the praises of the trial have been sung, the seamy side, so to speak, of the subject having been deferred. That there is a seamy side to the subject may be gathered by a glance at the trial border any time this season from June onwards, when those having life remaining were in full growth again. Compared with last year the display was far inferior. This is due largely to the numerous gaps that occur in the collection in consequence of the death of many kinds during the autumn and winter of 1897-8. But it may be said the winter referred to was remarkable for its mildness and dryness, so much so that the test as to hardiness is not a good one. But if severe frost was absent in great degree, the Chiswick gardens were long enveloped in poisonous fogs, and it is doubtless these that have played such havoc with the collection. All the same, it is very curious that it is not one stock or two wherein failures occur, but in all. This is a very remarkable fact. Therefore, putting aside the drawbacks of locality, if such exist, the only possible excuse for failure would appear a certain innate weakness of the variety itself. This at least appears the simplest and, indeed, to me the only feasible explanation that may be offered of the death of so many apparently good things in the first season. The failures would be of no moment were it not for the endeavour to distinguish the group as "border" Chrysanthemums, with which hardiness would appear more or less inseparable. As the matter now stands, there undoubtedly appears a certain proportion of kinds possessing a constitutional vigour that, rightly regarded, should prove of immense value

in the near future. If such failure is due to innate weakness of constitution, that kind should be marked as unsuited for future experiment. There is the so-called "rust" in the air, and judging by the wholesale manner it attacks plants, it will be well to take a stand by the side of the most vigorous kinds.

Quite early in the year I noticed many open spaces in the trial border of these things, and in subsequent visits I jotted down, I believe, the majority of the absences. These, I regret to say, include many beautiful things, which there is no need to discard in those instances where a summer display is made each year. At the same time it should be made clear that the same or similar colour exists in the more enduring kinds, so that the reason for retaining the former is minimized. Of the collection as a whole the journal of the society contains descriptions and marks bearing on this standard of excellence, given of course at a time when the enduring qualities of the plants had not been tested. In one other respect the collection as a whole has not equalled expectations in the second year. Planted so late as May 26, 1897, and generally in small plants, it was not unnaturally thought some varieties had scarcely done themselves justice, and that the established plants would not only have given a finer display of blossom, but a decidedly earlier one also. This latter opinion I also expressed, but owing to the heat and drought it has not been realised. Many kinds indeed were later by some three weeks in coming into flower than in 1897. It is due first to a very dull, cold, sunless time in April and May last, and secondly, to the great parching heat that so long prevailed in summer without atmospheric moisture.

The following are the names of the kinds failing, *i.e.*, kinds which appear to have vanished entirely, and may be of some use to those making a selection of the hardiest sorts: Mrs. A. J. Parker, October Yellow, Fred Pele, Edie Wright, M. Dubor, Doreis, Gloire d'Astafort, Searlet Gem, General Hawkes, M. A. Dufour, O. J. Quintus, Nanum, Mons. Foukabra, Mme. Leon Lassalle, Martinmas, Mons. F. Sysmayer, Mme. Gabus, Montague, M. Z. Lionnet, Gold Fleece, Mme. Eulalie Morel, Claret Belle, The Don, A. Gaby, Harvest Home, Myhett White, Sam Barlow, M. Chauchard, Mme. A. Nonin, Grace Attiek, October Queen, and Mme. Fredk. Usmayer.

The above may not prove an absolutely complete list of the failures, it is, however, complete in so far as the labels denote vacancies in the border, and while the foregoing list is a formidable one, it will be seen by comparing the report in the society's journal on the subject that a large majority of the very cream still remains. These latter indeed yielded a rich harvest of bloom during the past few months and well deserve their title of border Chrysanthemums. E. J.

Chrysanthemum John Shrimpton.—This is one of the best varieties I have tried for growing in small pots for grouping. If struck in May and placed in 3-inch pots nice little bushy specimens can be had by the time the principal stock is housed, and flower after these are over. If wanted to bloom in November, the cuttings may be inserted in April, the resulting plants being somewhat larger. The colour is bright red, and it has a fine appearance when grouped with the paler-coloured single kinds, such as Purity. I have not found a better kind in its colour for this purpose since the old Cullingfordi, which it resembles a little in habit.—N.

Single Chrysanthemum Miss Rose.—This is a beautiful variety and has been much admired here both for cutting and as a pot plant. It may be struck quite late in the season and yet flower well, but my best and most useful plants were struck in April. Three or four cuttings are placed in a 3-inch pot. As soon as ready they are placed in the 6-inch size and grown on as well as possible, keeping them well watered and syringing freely to ensure the foliage remaining

fresh and green quite to the base, for half the beauty of these charming flowers is lost when they have bare, leggy stems. As cut flowers for any kind of decoration they are first rate, and they last well in good condition.

Anemone pompon Chrysanthemums.—A correspondent lately referred to the great value of these small-flowering Chrysanthemums and mentioned Marie Stuart as a beautiful variety. I am glad to find this still finds favour, as for general decoration in conservatory or drawing-room or for cutting I consider it one of the very best in cultivation. Moreover, it is such a good grower, that spring-struck cuttings make dense bushes in 6-inch or 8-inch pots, and I have seen plants 5 feet in diameter from autumn-struck cuttings and furnished with hundreds of lovely trusses. Very little disbudding is needed, merely sufficient to enable the blooms to expand fully without crowding.—J. C.

NEW CRIMSON-COLOURED CHRYSANTHEMUMS.

It is a general complaint that whites and yellows predominate too largely in Chrysanthemums. Of course there is truth in it, and year after year they go on increasing. A pleasing feature, therefore, of the present season's novelties is that several notable additions have been made to the crimson shades. H. J. Jones, an English-raised kind, is a particularly rich dark crimson bloom. In size and form, too, it is not wanting. Lord Cromer has blooms of medium size, but of a very rich crimson colour and the petals are stout and lasting. A very handsome flower is Hon. W. F. D. Smith. The colour is dark crimson-purple, petals of exceptional length, drooping gracefully, and the build of the bloom is perfect. If it be constant and easily grown this sort will be highly esteemed. It is an English seedling and the flower noted was exceedingly well grown.

The worst of many English seedlings is that they do not improve by being generally cultivated. It would not be a difficult matter to name a goodly list which has been seen in fine form once, but seldom afterwards. Henry Weeks is yet another splendid crimson variety raised in England, and of fine colour and proportions. I hope this will prove constant like the variety of last year from the same source. J. Chamberlain is a truly grand Chrysanthemum, so rich in colour and lasting. John Pockett, indian-red, with old gold reverse, is a noble incurved flower and most distinct. This is an Australian kind of capital growth. From the same country came two sports from the well-known Pride of Madford, named Mabel Kerlake and Pride of Stokell. They are rich crimson-red in colour, being practically the same. Curiously, I met with a similar sport in Kent the other day. The grower with whom it sported has had it two seasons, but valued it lightly. It is, however, like the others, very fine. This, I fancy, is the first instance of a Chrysanthemum sporting into a new colour in such far-off places at most likely the same time. Mme. Rene Solomon is likely to be an acquisition as regards colour. It is quite a crimson-brown. The flower is full and well formed. Mr. T. Carrington has blooms of fine dimensions, and will thus be of value to exhibitors. It is rosy carmine in colour and of noble build. A remarkably rich shade is found in Purple Emperor. This gives blooms of medium size, the florets being somewhat short. Master H. Tucker improves on further trial, and is now a gain as regards colour, besides other good qualities. Secretaire Pierens has flowers of a rich hue when opening, but with a somewhat faded look when fully out. Royal Standard, so highly thought of as a crimson sort last year, has not fulfilled expectations—at least with me; nor does David Inglis appear likely to be much cultivated.

I sometimes think we discard old sorts too readily. F. A. Davis, or Jeanne Délaux, as it was seen some ten years back, was a very fine crimson

Chrysanthemum. The variety E. Molyneux still holds its own and has been noted in good condition in several instances this year. Nyanza and Beauty of Castlewood also are magnificent flowers, but rarely well grown, and William Seward, like the rich-coloured G. W. Childs, is gradually going out of cultivation owing to the prevailing taste for varieties of huge size. H. S.

POPULAR SHOW CHRYSANTHEMUMS.

With the great wealth of new varieties introduced annually it is strange that so many older standard sorts still claim so much favour among exhibitors. One has only to critically examine the reports of shows or note the varieties

growers. "C. H. P." gives a list of some of the foremost favourites in the older standard sorts; if he would give a selection of some of the modern novelties that growers need as an augmentation to the existing stock, I am sure many inexperienced readers would benefit. Those who have to depend solely on catalogue descriptions in making a choice find a difficulty when their purchases are measured by small numbers. Since the introduction of so much novelty in the incurved section, it has begun to revive an interest that was fast declining, both among growers and the public who patronise the numerous shows. There is no doubt that some among the new incurved are a distinct gain to that section, and from a grower's point of view a stand containing a good proportion of new ones is as interesting as

Marie Louise Pear tree in bloom. (See p. 525.)

staged at some of the best provincial exhibitions to see what a large proportion of older varieties is shown. There are undoubtedly a great many new varieties that are disappointing, and not a few are grown one year to be discarded without further trial. This is to some extent the outcome of the variable influence of the season in which they are grown. The past summer has been one that has furnished many difficulties, particularly where a short water supply prevailed. But for the great number of growers who compete, shows must of necessity suffer in such a season as that now closed, for the fact is admitted that many collections this year have been below their average in quality of bloom. The leaf rust, too, spoils the chances of some otherwise good

one containing Japanese kinds. The older Queen family is now fast declining in popularity; it will be lost to cultivation in a few years' time, judging by its scanty representation at the late shows. It is a pity the single, pompon and Anemone pompon sections do not enlist the attention of growers and societies more than is done. Classes for these, if well contested, would make a bright and varied feature, to my mind far superior to the formal and often ugly reflexed kinds which find a place in many schedules, and often make a scanty and uninteresting display. The singles are certainly making headway, and the interest in them is stimulated by the numerous novelties submitted by a few of the leading specialists.

ORCHARD AND FRUIT GARDEN.

STOPPING YOUNG VINES.

THERE still exists a difference of opinion as to whether young Vines should be stopped during the first season of growth or allowed to grow unchecked. Old Grape growers believed in letting growth go unstopped to the top of the house and even down the back wall, and a few when planting cut-backs allowed the lower as well as the terminal eyes to extend their growth, thus having as many as seven or eight rods to one Vine, each striving to outgrow the other. The laterals were not even stopped, and by the autumn the house presented a perfect thicket of wood. The idea was that as a Vine made roots in proportion to the growth this extra amount of wood and foliage resulted in the formation of a numerous colony of fibrous feeders, and that hard cutting back being practised, grand fruiting rods were made the second year.

The late Mr. William Thomson was strongly in favour of this system, and all will admit that in the early days of the Clovenfords vineyard he grew grand crops of Grapes. One or two of the large vineries at Hutton were also treated similarly, Mr. McIndoe, I believe, having no cause for regret. I am aware some have characterised the system as a waste of time, there being no length of rod left for bunch production the second year, but if it can be proved that the future cropping powers of the Vine are greater than in those which are subjected to restriction the first year, then there is a gain in the end. Vines that are stopped the first year ought to be strong and vigorous, as if at all weakly they seldom make anything but a spindly growth afterwards. Market growers generally stop the young Vines the first summer when a few feet of growth have been made, with a view to securing plump eyes at the base of the rod for producing bunches the next year, and as they feed liberally and only expect their Vines to last a comparatively short time, early stopping is perhaps best. Much, however, depends on the strength of the Vines and the culture given. A mistake sometimes made by those having had but limited experience is permanently stopping the leader when the top of the trellis has been reached and keeping all laterals closely pinched also, the result being bursting of the eyes lower down the rod and the practical ruin of the Vine. A little growth should be allowed on the topmost laterals to carry off the sap.

J. C.

Fig Negro Largo forced.—Although this Fig is a capital sort for growing in pots, my experience is that it will not force. Even on well-ripened trees the few fruits which formed on the extremities of the previous year's wood fell off when they had swollen to the size of horse beans, and the majority of the shoots showed no fruit at all. It wants to make new growth ere the fruit appears, and on this there is usually abundance of Figs. Well established trees in medium-sized pots, if top-dressed and liberally fed, swell off large highly-coloured, deliciously flavoured fruit. If introduced into a light, sunny house early in March, ripe fruit will be forthcoming at the end of July and during August. Negro Largo hangs in good condition longer than most Figs.—N.

Apple Gooseberry.—I remember this Apple being planted in Essex more than thirty years ago, which was, I believe, when it was first introduced. Gardeners expected great things of it, but for a good many years after planting I do not recollect seeing a really good crop of fruit on it. It is a large handsome Apple, excellent for cooking and, I believe, a good keeper. The

only reason I can think of for its not being generally grown is its shyness in bearing, resembling in this respect—at least in a young state—Blenheim Orange, Bramley's Seedling, and Peasgood's Nonsuch. I believe the Gooseberry Apple is still sold by a few nurserymen, and if any readers of THE GARDEN have it I shall be glad to hear their opinion of it.—J. CRAWFORD.

A great Grape class.—In commemoration of the holding next year of their twenty-fifth exhibition the executive of the Shropshire Horticultural Society purpose offering at Shrewsbury in August next a sum of not less than £100 in prizes for twelve bunches of Grapes in six varieties, two bunches of each variety only being shown. Whilst the sum offered is most munificent, no doubt interest will be largely excited as to the number of prizes into which this big sum of £100 will be divided, as the extent of the competition will be doubtless largely determined by the numbers of the prizes. Certainly the result of such a class should be to bring together the finest examples of Grapes in the kingdom from those gardens where a sufficient number of varieties is grown. For the first time in the history of this great exhibition foliage effects will be sanctioned in a Grape class, and whilst any length of Grape beads, howsoever superb the bunches on them, looks somewhat monotonous, it will in this case be possible to break up that monotony by the introduction of a few plants and some pleasing foliage. As space is to be severely limited in length, it seems evident that the boards will have to be arranged in tiers one behind the other, but it is hoped that tables will be so constructed as to enable that form of staging to be easy. The Royal Horticultural Society's code of judging rules will constitute the guide for the judges. To northern growers perhaps August may be rather early, but having long prior knowledge of the class they can take needful steps to accelerate their Vines if desirable.—A. D.

Drying off v. ripening off.—We have been so accustomed to look for abundance of colour in fruits and foliage after a hot summer, that it has come as a surprise to many to find that Apples are not nearly so highly coloured this year (after one of the hottest and sunniest of summers) as they usually are after one of our dripping and cloudy seasons, while foliage has kept remarkably green and hung on the trees until an unusually late period. At the great fruit shows in the metropolis and Crystal Palace it was singular to find the Apples from the western counties better coloured than those from the south, or even from Kent, with all its advantages in many ways for fruit culture. I think that anyone who was daily taking note of the fruit trees during the long protracted drought could come to no other conclusion than that the lack of colour was clearly the effect of want of moisture both at the root and in the atmosphere, for even where artificial watering was resorted to the atmosphere still remained unusually dry and calm, and I have a strong suspicion that a very calm period does not promote high colour, and artificial watering, although a great help, can never replace the lack of rain water. Happily, the process of drying off plants, under the impression of ripening them off, is nearly a thing of the past, and the sooner it is given up the better, for certainly one of the lessons taught us by the late protracted summer is that sunshine alone will not give high colour unless accompanied by a corresponding amount of rain, so that the trees can perform all their functions without a strain.—JAMES GROOM, Gosport.

Filberts and Cob Nuts.—Except in a few districts, Filberts do not receive the attention they deserve, and even where grown they are often accorded an unfavourable, out-of-the-way position, where they easily fall a prey to such enemies as the squirrel and nuthatch. The former devour the Nuts wholesale, while the nuthatch, a small bluish coloured bird with a powerful bill, carries them to a gate-post or tree, and,

after fixing the Nut firmly in a crevice, quickly hammers a hole in the shell and devours the kernel. The trees are, therefore, better planted where they are under the eye of the gardener, and more likely to receive attention and to be kept free from an undergrowth of weeds and rubbish. Although the common Hazel Nut is found growing and fruiting freely in shady woods, the finer kinds do better in a fairly sunny position, the husks of such fine varieties as the Prolific Filbert colouring beautifully and looking very handsome in the dessert. Both Filberts and Cobs will thrive in a soil that would starve the majority of fruits, but for all that they pay for a decent soil and an annual mulch of good farmyard manure. If of sufficient depth to allow of trenching, the ground should be so treated, working in a liberal supply of well rotted manure, doing the work early enough to allow of it settling well previous to planting. This is essential both to keeping the roots at home and for the retention of moisture the first summer. The trees are sold both in standard and dwarf forms, the latter, perhaps, being the better for ordinary culture, having a clear stem of about 2 feet or 2½ feet, so that the hoe can be worked beneath during summer. Fine crops of Nuts may be grown on trees which are allowed to make a free, unrestricted growth, provided the centres are kept open and all spray and weakly growth removed. The finest produce, however, comes from trees having a limited number of main branches, these being closely spurred in. Young trees will need watering the first summer if dry. The best sorts are the Prolific Filbert and Kentish and Webb's prize Cobs.—NORWICH.

GARDEN WALLS.

A CORRESPONDENT recently asked for the best materials for training trees on walls that have just been erected. I have never found anything better than the cast nail in various sizes, which can be broken off rather than drawn when not required, and medicated shreds with tar twines, known as Nos. 202 and 302 respectively, for small, medium and large branches. This will reduce to a minimum any harbour for insects. The query, however, opens up the wider question as to the advisability of building garden walls in these days, and I should answer it most decidedly in the negative. The two points designers of gardens had in view in bygone days, when the first thing to be done was the building of a wall 10 feet or 12 feet high in a square or rectangle, as the position required, were accommodation for choice fruits and protection for things within the enclosed area. I am writing solely of kitchen garden walls, and have nothing to say against the erection of low walls or arches in suitable places for the growth of beautiful climbing or trailing plants. Shelter can be provided quite as effectually, more cheaply, and certainly adding far more to the beauty of the garden if belts of quick-growing evergreen trees are planted on the north side of the fruit and vegetable garden from west round to east, whilst so far as the accommodation for choice fruit is concerned, the cheapening of woodwork, glass, and all matters in connection with the heating apparatus enables orchard houses to be run up even at an initial cost not exceeding what would be paid for garden walls; and certainly, when one considers the safety of the bloom under glass and the ability to dispense altogether with all protecting material, would give a monetary balance in favour of the orchard houses. A lot of sentiment hangs about old garden walls, and personally I would not advocate their removal, but certainly would never copy them in the formation of a new garden. I have had rather more than my share of them, and it is not an easy matter to grow good fruit where they are battered and knocked about with close on two hundred years' nailing, and no facilities exist for filling in the holes except with a home-made mixture that is put on as time and circumstances permit. In lieu of walls I would strongly recommend a couple of span-roofed struc-

tures for early and mid-season Peaches and Nectarines, orchard houses for early Cherries and Plums and cordon Pears, and the bush system of culture for any other fruits that may be required. In the erection of houses for fruit growing, private gardeners have much to learn from market growers, who run up something that answers the purpose admirably at a minimum of cost.

I have been led to these suggestions partly in following the query in a recent issue and partly from an inspection of the work of a local market grower who has just decided to make a start with Peaches and Nectarines in addition to his Grapes, and is covering half an acre of ground with glass for the purpose. Every provision for the well-being of the trees is made, and at the same time every bit of ground is utilised at the lowest possible outlay, and those on the point of laying out new gardens and who contemplate building long stretches of brick or stone walls may well hold their hand until they consider if better and, in the end, more economical provision for fruit growing cannot be devised. Replying to the query as to staples, I should say that staples driven into the wall 15 inches apart would answer the purpose for all climbing plants and those fruit trees that, once established, will be pruned more or less on the spur system, as dessert Cherries, Plums, Pears, and Apricots. Temporary lengths of small, but firm wood that may be made from the annual cutting down of hardy Fuchsias can be used for the young growths as required and removed as the branches increase in size, and can be secured to the staples. It is not advisable to let the two come into immediate contact. I quite fail to see the necessity for elaborate lattice-work of Oak, Chestnut, or Bamboo. For Peaches, Nectarines, and Morello Cherries I should recommend galvanised wire as the neatest, most lasting, and consequently the most economical method. There is not the slightest risk of damaging the trees if care is taken in the tying in.

The outcry against the wire is well enough in its way as a precaution, but it may be pushed too far. There are scores of places where it is in use in which splendid crops of fruit are annually produced. I have no special brief for the wire, but—give it a hearing. The market grower I have mentioned in the notes will train his half acre of Peach trees on galvanised wire.

Charenton.

E. BURRELL.

Apricot pests.—As a rule the foliage of Apricots is not subject to attacks from aphid or red spider in the same degree as that of the Peach and Nectarine. All the same, it has its enemies, which must be promptly dealt with, or the trees and crops soon suffer. At this time of year the trees should be closely examined, and if any brown scale is visible, means at once taken to eradicate it. I have found no insecticide to equal soluble paraffin, diluted according to instructions on the tins. Let the trees be well syringed, repeating the dose in a day or two. If badly affected, the branches should be brought away from the wall, so that every part of the tree can be reached with the mixture. When carefully applied I have never known it to fail. By

its use also labour is saved, as no second man is required to keep the mixture in motion, as is the case when ordinary paraffin is mixed with water.—C.

Peach Stirling Castle.—I am pleased to find that both "Hortus" and Mr. Wythes grow this Peach. The former speaks of it as not dropping its buds, and this is my experience. I think no early Peach house, where the fruit is wanted, say, in June, should be without a tree of Stirling Castle, as with a good root condition and ordinary treatment a crop of fruit is certain. A friend of mine used to start the tree about November 20, and invariably gathered fine ripe fruit the last week in May. The tree was thoroughly established, and used to swell its buds as soon as a gentle warmth and moisture were supplied. As a correspondent recently observed, young Peach trees do not as a rule force readily, age being wanted before one can really rely on the trees for free and constant cropping. As

if fruiting has commenced, and to water well once or twice during the summer. When free from grittiness, I look upon Beurré Diel as a most valuable Pear, as it keeps such a long time.—N.

Keeping Grapes in bottles.—I read with interest Mr. Tallack's recent remarks on keeping Grapes in bottles in winter. I, like him, cannot see any advantage in putting charcoal into the water. The bunches which had no charcoal kept just as long and as well as those that had it. As Mr. Tallack says, there is always a risk incurred in adding fresh water to the bottles, as some is likely to be spilled and find its way amongst the berries, starting decay. It is nice to have a Grape room, as once the bunches are placed in it there is no further trouble in moving them, but I have kept Alicante, Lady Downe's and Trebbiano perfectly sound and plump till April by standing the bottles on a brick ledge close to the front lights of a span-roofed vinery, only, of course,

The White Heart Cherry in bloom. (See p. 525.)

"Hortus" observes, the blooms of Stirling Castle are always furnished with plenty of pollen, which is useful for fertilising other less certain varieties in flower at the same time.—J. C.

Pear Beurre Diel.—At page 428 "J. H." gives his experience with this handsome late Pear. Referring to its grittiness—a fault it has in more gardens than not—he expresses an opinion that want of sufficient root moisture is in the main accountable for it, and recommends liberal supplies of water as at least a partial remedy. I am inclined to think "J. H." is right, as an old tree I had under my charge yielded very fine fruits which were more or less gritty. Occasionally, however, the quality was much more juicy and free from grit. I kept no memorandum, but, had I done so, I should doubtless have found the improvement occurred in moist seasons, as then the foliage and fruit as well as roots got more moisture. After these experiences it would be advisable for those planting or already having young trees, to mulch the roots liberally, at least

those that were left had then to be moved to other quarters when the vinery was washed and prepared for starting. I have kept Grapes sound for a considerable time by inserting the laterals in Mangold Wurtzels and laying these along a fruit room shelf, the upright edge keeping them in position.—J. C.

Mulching Strawberries.—Strawberry beds occupying fairly retentive soil were this season none too moist when the crop was swelling off and ripening, but where the situation was high, with ample drainage, and the soil light or sandy, those who did not mulch their beds early enough to prevent what moisture there was in the ground from escaping will, I fear, in many instances have had the annoyance of seeing well-cropped plants partially collapse before maturity was reached. With some gardeners no mulching is given beyond one of strawy material or bracken in summer to keep the fruit clean, and in ordinary seasons and fairly strong soils no harm may occur from the omission of autumn or early spring

coverings of short manure, but I have had soil to do with which in extra dry seasons, unmulched before March, would have become so parched to the depth of the Strawberry roots from undue evaporation, as to cause both foliage and fruit to collapse. What I like best is to well mulch in November or December with short litter from the piggery, taking care that this is well saturated with the urine. By winter rains this is washed clean and the roots nourished, the labour also of mulching when gardeners are always busy is avoided, and thus two birds are killed with one stone.—C.

Apple Ribston Pippin.—Judging from the number of dishes of Ribston Pippin shown at the Palace show, it does not seem that the idea of some that this variety is dying out is correct. The Ribston can be grown as well as ever, provided a warm, well-drained soil and sheltered situation are given. It does best as an espalier worked on the Paradise stock, fruit from such trees, if not unduly shaded by allowing too many spurs to form, growing to a large size and colouring beautifully. The Ribston is not suited for orchard planting, as the trees never make large heads and seldom live to be old. I have known orchard trees have plenty of bloom several years in succession, yet not produce a single peck of fruit, a few cutting winds seeming to paralyse the bloom.—J. C.

Peach Prince of Wales.—There are a few Peaches of good flavour and good setters and bearers that are nevertheless seldom seen or heard of. Amongst the number is Prince of Wales. True, its shape is not handsome, being rather rough and irregular, but it usually colours nicely, and as to its flavour, I do not think much fault can be found with it. The blossom is very small, but it invariably sets freely, while I never knew its fruit to fall when stoning, which most varieties are apt to do mere or less. I have only grown it under glass, and have never attempted to force it, but allowed it to come on gradually with the aid of husbanded sun-heat. This treatment suits it well. Although not a thick-skinned Peach, it bears handling and travels well. From its behaviour under glass I am inclined to think it would do well out of doors.—NORWICH.

Trellis for walls.—I note at p. 458 the editor gives some excellent advice as to the use of Bamboo for attaching fruit trees to walls. Bamboo canes are not costly and they are lasting, but in some places they are not to be had, and in such I used common laths, such as plasterers use, and they answered well. They may be had in lengths. Mine were 5 feet, and the walls being 11 feet, two gave me the length for the wall in height at 1 foot from the soil. They were fastened to the wall with nails and lasted from six to nine years. Of course, once up they were not removed. It was a rare occurrence for the laths to get loose. Each set of laths was placed at 15 inches apart and there were no cross-pieces. With fan-trained Peaches or Nectarines these are not needed. I am unable to give cost of this mode of training, but it is very small; a bundle of laths goes a long way. After fixing the laths they were studded with nails or eyes to tie to, but this training is only advised for Peaches or Nectarines.—G. W.

Planting young Apricots.—The time is at hand when lifting and planting Apricot trees will have become general. One cannot too strongly condemn the common practice of planting young trees in the same soil as the old trees occupied. True, a little fresh compost is usually placed over and around the roots, which is all very well as far as it goes, but they soon pass through this into the original compost, the exhausted character of which was probably one of the chief causes of the collapse of the old trees. I am aware making new borders of maiden loam which has to be prepared is both an expensive and laborious operation, but there is really no need for this, all that is needed being to take out a few feet of the old border for a start and to replace it with average kitchen garden soil. To this add a small quantity of newly-cut turf,

abundance of lime siftings, old mortar or plaster refuse, and wood ashes, these ingredients being thrown in and mixed as the work proceeds. This will grow Apricots well, and the risk of the trees making gross wood for the first few years, as is often the case when planted in rich loamy borders, is greatly lessened. Let the new border be thoroughly well firmed and planting completed, well watered, and the trees mulched. Owing to the excessive drought, trees will, I fear, lift none too well, but purchasers should see that what fibrous roots there are are preserved in as good a condition as possible by arranging with the nurseryman to envelop them in some well-moistened material. If this is not done, wood-shrivelling may be expected, this affecting the whole tree more or less, and giving it, to say the least, a bad start. Wherever practicable, it is a good plan to visit the nursery in good time, selecting the trees and having the purchaser's name affixed. I should add that it is always advisable to raise Apricot borders somewhat above the surrounding level, this being still more important in low-lying, damp situations.—J. C.

SCARCITY OF WINTER PEARS.

THE season generally has not been favourable for an abundant, or even an average supply of autumn Pears, and the prospect for winter use is much less so. During October and November there is abundance; indeed, many more than are required, but by the end of November the list is considerably lessened. To those who depend on the fruiterer for their dessert this is not so much a matter of concern, because of the supply of foreign Pears which come to us in such fine condition. There is a wonderful influence brought to bear on the keeping of Pears in the fruit room in which they are stored; in one they keep so well as to extend the season of almost any one sort days longer than can be done in another, when to outward appearance and in construction the one would seem as well fitted for the purpose as the other. It is an easy matter to provide a quantity for October and November from almost any building, but the test comes when November sorts are expected in the following month. I know of a small garden in this neighbourhood in which is a fruit room that is remarkable in affording a long succession of Pears. Varieties which in my own case would be in use say in November can easily be kept well into the next month, and yet the position, being east, would not apparently be so favourable as in my own case, where the fruit store is against a cooler and lofty north wall. It is not an easy matter to explain why this should be so, but the fact remains. As I have previously intimated, winter Pears are by no means plentiful either in variety or quantity, birds, wasps, and spring frost each severally accounting for partial crops to gather in, and in the matter of variety there is not so much choice. At present, Napoleon Savinien affords the larger bulk; this the garden enemies did not presumably find good enough in a green state, and there is unmistakable evidence that birds and wasps have a strong instinct in finding out the best quality in Pears or Apples. Winter Nelis is a variety that, although ripe enough for dessert in November, can be kept until December without going rotten at the core as some sorts do. Josephine de Malines, often described as a January Pear, cannot always be kept so long. It is, nevertheless, a good keeper and a deserving variety to plant. Ne Plus Meuris extends over a longer season than any other I have, and although its quality is not of the best, it is useful on that account. Even if it does not ripen fast enough or its quality is not quite good enough, it can be used for stewing. Easter Beurre, so far as concerns its name, is a misnomer. I have never been able to keep it through January, and Christmas can often be taken as its season rather than Easter. Though not of high quality or so late as indicated by its name, it is none the less a useful sort. Glou Morceau is a good or an indifferent Pear according to the age of the tree and the soil

in which it grows. Bergamot Esperen may be mentioned as a useful late sort, though small, and, like Ne Plus Meuris, a free and constant bearer. W. S.

Hills.

Pear Comte de Flandre.—I have had no previous experience of this Pear, which is now ripe, it having fruited for the first time this year. It possesses a finely-grained buttery flesh, is juicy, and richly flavoured, and the size of the fruit is from medium to large. The trees I have are single cordons growing on a south-west wall, the growth of which is fairly vigorous and quite healthy. Another season's trial is necessary before giving a final opinion, but so far it appears to be a valuable variety if only from the fact of its ripening at the end of the year.—A. W.

Plum Grand Duke.—As an espalier-trained tree for an east wall I find this a very useful blue Plum for August use, and, like Prince Englebert, which "Norwich" mentions, it is a good keeper. It bears very freely, and when quite ripe is not despised for dessert, though there are other Plums ripening at the same time which claim a higher character for quality. As a cooking Plum it might be planted without any doubt when variety is desired, and for every-day use there is need for this, even if the same uniformity of quality is absent. It has, like some other blue Plums, a very dense bloom, and when required for dessert demands care in gathering, or much of its beauty is lost.—W. S.

Peach Dagmar.—This is, as "C. N." says on page 459, a free bearer and an easy variety to grow, and thus would make a good amateur's Peach. In the smoothness of the skin it is, I think, the most distinct of all Peaches—at any rate, I cannot recall another variety that will compare with it in this respect. With me it is rather under than medium-sized, but as my trees are young, the fruits may improve in size as they attain age. It is a pretty Peach in shape and colour, and to those requiring variety it might be strongly recommended. Like "C. N.," I can speak of it only as an indoor variety, though I do not see any reason why it should not be equally suitable for outdoor planting.—W. S.

Currants as pillar trees.—Garden walls of considerable height are usually furnished with pillars for strengthening them. Red and White Currants thrive exceedingly well trained on these. Trees with three main upright branches are the best: these if kept closely spurred in and well nourished at the roots will bear regularly and well. Both the red and white varieties may be grown in this way, those which make straight growths being preferable. Pillar-grown trees have the advantage over ordinary bushes in various ways. The fruit can easily be protected from birds and the foliage kept free from insects by the use of the garden engine. An east wall is as good a position as any, and here the fruit will hang a long time in good condition. Pillar Currants also have a very ornamental appearance. One of the largest and best Red Currant trees I ever saw grew on the east end of a cottage in South Notts. It almost covered the end of the building, and when in fruit was quite a picture.—J. C.

Apple Maltster.—I notice in a recent issue a letter from Mr. Crump respecting this Apple. Tastes differ about most things, but personally I should not class Maltster as a highly flavoured dessert Apple, and although I know at least one large grower of fruit for market who strongly advocates this variety, it is not one which has ever been in much demand with the general public. My object in writing was not, however, to discuss the merits of this Apple, but simply to state what I know about its hardiness. In 1880 and 1881 we had two very severe and protracted winters, and we had a number of these trees which were forty years old killed down to the snow-line. The trees were situated in a large orchard of some 32 acres, which is planted on the slope of a hill. Maltster occupied a square

of about an acre on the table-land at the top of the hill. The trees were surrounded by other Apple trees on three sides, viz., north, east, and south. Not one of the other Apples was injured, but every Maltster died, and the place they occupied may be seen to-day. The trees were standards worked on the wild Crab, and the stems would be as thick as a man's thigh. Since witnessing this I have always fought rather shy of Maltster, and should certainly not recommend anyone to plant it in a cold district. I ought, perhaps, to say that we generally register as many degrees of frost at Chilwell as anywhere except Loughboro', which station is always an easy first to anything south of the border.—A. H. PEARSON, *Chilwell, Notts.*

NOTES AND QUESTIONS.—FRUIT.

Nectarine Hunt's Tawny.—One rarely sees a note on this very useful early Nectarine. It is too good to be allowed to drop out of cultivation. I have not grown it for some years, but used to be very fond of it. Certainly the fruits are rather small, and this possibly prevents its being much grown, but it is delicious when well finished and the colour of the fruits inside and out was much liked. The tree is a good and very healthy grower, and invariably fruits well.—J. C. T.

Apple Tyler's Kernel.—All that "W. I." has to say in praise of this Apple (p. 461) is well merited, and it is indeed a very free-fruited valuable sort. At the recent Crystal Palace fruit show I noted several excellent dishes of it, and one in particular, but by whom it was exhibited I now forget. These fruits were remarkable for their size and high colour, and I doubt whether they would have been recognised by growers in the county of Hereford, where the variety has long been known and cultivated. It is a first-rate market Apple.—A. W.

Pear Comte de Lamy.—Mr. Crawford is to be commended for drawing attention to this highly flavoured little Pear. In my opinion no garden where soil and climate are suitable for fruit growing should be without it. I have met with it in very many parts of the country, and growing in a great variety of soils, and also had a good deal of experience with it in the east of England. In all cases it was a success, both as regards flavour and cropping, and the same may be said of its behaviour here.—A. W., *Stoke Edith, Hereford.*

Apple May Queen.—At the first exhibition of Chrysanthemums and fruit recently held under the auspices of the Malvern Horticultural Society, this too little known late dessert Apple was shown in excellent condition by various exhibitors. So far I have never met with it out of Worcestershire, which is its native home, but two or three nurserymen now catalogue it, so that ere long we may reasonably expect to find it better known and more largely grown. It is an excellent variety, the fruit, which is highly flavoured, keeping well into May, while it is a free bearer.—S. E. P.

Apple American Mother.—"C." Norwich (p. 117), writes that he was unaware until lately that this variety would make a good pyramid. It also succeeds and bears well as a bush, the fruits on which are generally very highly coloured and richly flavoured. I have seen it exhibited very frequently at fruit shows this autumn, and in the majority of instances in good form, both as regards size and colour. It is a capital table Apple, and, as "C." justly remarks, no garden should be without at least one tree of it.—A. W.

—I recently saw some beautifully coloured, large fruits of this variety. At page 417 "C." notes the excellent qualities of this variety when grown as a pyramid. I find grown as a cordon it does not like the severe pruning necessary to keep the trees in shape. On the other hand, it cannot be termed one of the best doers in wet, cold soils. I find I get the best crops from bush or pyramid trees not severely pruned. I lift every few years, this promoting a fruitful growth. The quality of the fruit is not nearly so good when grown on a gravel subsoil. It grows well in the north, as I have seen excellent crops in Scotland. In my opinion many could grow this variety if they gave it more freedom of growth. Of course, soil is equally important, as I notice, in spite of made borders and the best

culture in some gardens, it has given a very poor return.—S. B.

FLOWER GARDEN.

ZAUSCHNERIA CALIFORNICA.

ONE of the many pleasant things in connection with gardening is the willingness of others to come to one's assistance when in a difficulty. I have had a fresh instance of this in the communications regarding *Zauschneria californica* which have appeared in THE GARDEN or which have come to me privately. To these correspondents I have to tender my best thanks before referring to their remarks in detail. What I said was not the result of isolated experience, but of a somewhat wide interchange of observation. If one's notes were despondent, they have had the effect of eliciting more cheering experiences, which may give some of us courage to try again. Yet it is doubtful if we have found the secret of success, because under apparently similar or closely related conditions in different gardens the *Zauschneria* blooms or fails to bloom for inexplicable reasons. With its hardiness few of us have any fault to find, but the test of its usefulness in the garden is its flowering, and in inducing this we have much to learn.

I have no knowledge of the precise conditions under which it is grown in the Cornish garden to which I referred except from the note which recently appeared in these pages from Burgoose. I have, however, the following note from a hot, dry garden in Gloucestershire, supplementary to a laconic, but expressive one a short time ago, which was: "Discarded: runs about, but will not bloom." The following is now to hand: "I have just been reading your note on *Zauschneria* and *Plumbago Larpentea*. I have discarded both. The former I grew on a very high and hot rockwork, and it ought to have blossomed."

To Mr. H. Selve-Leonard, Mr. F. W. Burbidge, and Mr. S. H. Boyle I have to tender thanks for their notes in your issue of December 17. The only other plan to induce the plant to flower which I have not yet tried is that of growing it in a wall. I do not care for growing plants under glass and then planting them out to flower. Mr. George Walpole, whose success with the *Zauschneria* in the charming garden at Mount Usher is referred to by Mr. Burbidge, has kindly written me giving full details of how it is grown there. Grown for some little time with little care it gave but little flower. Its rambling habit caused it to require cutting in, and some of the pieces which were thrown into the river got washed in between the dry stones of the river wall. There some of them took root, flourished, and gave a full show of flower. The wall, which faces south-west, was planted with the *Zauschneria* between the joints, and a sheet of well-developed blossoms results. It has also been tried on a wall away from the river facing S.E. by E., where it promises well also. I regret that in observing the many features of interest at Mount Usher while there in June I had not asked about the *Zauschneria*. So interesting a garden cannot be seen in a short visit. One is tempted to quote from a letter from Mr. Osgood Mackenzie from Poolewe, N.B. Mr. Mackenzie says the *Zauschneria* is of no use "in an ordinary situation (say in a shady rockery), but at the foot of a south-west wall on a high exposed terrace it flowers fairly well every year." My obliging correspondent says that a plant from his garden which went to Tulloch Castle, on the east coast of Ross-shire, bloomed

well and regularly in an ordinary border in rich, stiff clay.

One would gather from the comparison of experiences that latitude has, within a certain range, little to do with the behaviour of this plant, but that it depends upon some other conditions, which we must be able to furnish or confess ourselves beaten. I am inclined to think that clay will be found the best soil for this plant, whose flowers so many would like to see in their gardens.

As one expected, the further correspondence upon this plant shows considerable discrepancy of experience. To all those who have contributed to it allow me to give my best thanks. Had nothing else come from it, the valuable note by Mr. Burrell would have justified the opening of the question. The day before publication of THE GARDEN of December 24, a friend who had had unsatisfactory experience with *Z. californica* sent me a note telling me of the early-flowering variety referred to by Mr. Burrell. Of the others I had known, but that which flowers in July had not come under my notice. This variety will be invaluable to many who cannot bloom the others. If my remarks were too depreciative, some allowance must be made for years of disappointment. Some of the remarks regarding *Plumbago Larpentea* which have appeared are founded on a misapprehension of what I said. If your correspondents will refer to the article, they will see that the *Plumbago* was only mentioned incidentally, and that what was said will not bear the interpretation they put upon it. In a recent article I said that *P. Larpentea* flowered regularly with me on a dry, sunny rockery. In conclusion, I hope to have the satisfaction of growing the early form of *Zauschneria* and to have the pleasure another year of speaking favourably of it.—S. ARNOTT, *Carsehorn, by Dumfries, N.B.*

—As one who has a vivid recollection of the enthusiasm which the late Donald Beaton, of Shrubland Park, evoked for these two Californian plants, I have been greatly interested in the instructive discussion that has recently occurred in regard to both, but especially the *Zauschneria*. On the dry soil of Shrubland and in many other easy situations both the plants proved hardy at the foot of a wall or with the shelter of a rockwork. The *Zauschneria*, however, is the more tender of the two, and a handful of dead Braeken is a safe protection in winter and spring. In the further north to which Mr. Arnott refers the plant is worth wintering under glass and planting out in favourable sites for blooming towards the end of May; but in East Anglia and elsewhere I have found both these plants thrive and bloom best under hardy treatment. I also like Mr. Burbidge's suggestion of growing the *Zauschneria* on walls, and would like to see the effect of *Plumbago Larpentea* grown in mixture with it. Failing this, the old *Linaria Cymbalaria*, all too little and seldom used as a wall clover, would form a charming background for the glowing brightness of the Californian *Fuchsia*. Not a few of our semi-hardy plants do not bloom or are killed outright through overfeeding and excessive supplies of water at the roots. It is, in fact, too often forgotten that a semi-starving regimen and free exposure to light and air are the chief conditions of free and profuse blooming. The *Zauschneria* and *Plumbago* go well together; the orange-scarlet flowers of the former contrast well with the bright violet or blue of the other. Neither is of much value for cutting, but in these days, while the majority of our plants are cut to pieces almost before they reach perfection, it is a special pleasure to come upon groups or masses of these two brilliantly effective plants in the garden for several months in the year, and saved from cutting through structural and constitutional characteristics. It is pleasing to find, through the numerous favourable notices that have appeared in your pages, that though the late Donald

Beaton's high ideals of these plants were hardly realised, yet both have proved very showy and useful in many situations.—D. T. F.

Violet Marie Louise—I planted last May a bed 30 feet by 9 feet. The runners were taken from old plants that had been growing in frames through the winter. The ground was deep and roughly dug. No manure was applied at the time of digging. Before planting I gave a top-dressing of bone-meal, wood ashes and fowl droppings, the whole being thoroughly well mixed together, spread on the surface, and well raked into the soil. The plants were set out 1 foot each way, all runners being taken off as soon as they appeared. In the third week in July I gathered the first bunch of Violets, and from that time up to the present I have been gathering from six to fourteen bunches every week. The plants have had frequent dressings of the same mixture and heavy waterings. The bed is in the open, having no protection whatever. Many of the flower-stalks are carrying two blooms.—RICHARD NISBET, *Market Drayton*.

Retarding Iris bulbs.—In his interesting and instructive remarks on Iris culture (p. 471) "E. J." refers to the uselessness of planting the Spanish Iris late with the idea of securing a successional batch of bloom. I used to grow many hundreds of this beautiful species for cutting, than which nothing is more suitable, and, thinking to lengthen the flowering season, I planted a portion of the bulbs in October, keeping the remainder on a shelf in a cool room till the new year. At first growth seemed satisfactory, but in the end it was weak and the blooms poor, expanding at the same time as those of the autumn-planted batches. After that I secured a succession of bloom by planting on various aspects, which is the only way it can be done. They did remarkably well in my light soil on a north border, but I could never induce them to do well the second year, although in a neighbour's garden, in a stronger soil, they lasted several years.—J. C.

A NOTE FROM SMYRNA.

MR. E. WHITTALL, in a letter to us from the above-mentioned place, dated December 15, says: "If I have delayed in replying to your kind letter of August 18, I have an excuse in the many anxious moments of the past six months. The massacre in Crete cost us the life of a trusted agent and the destruction of our offices, in which he was burnt alive with our whole staff of porters, &c.—some twenty-five souls. The resulting wave of fanaticism over our province brought danger still nearer home. Then all the crops in this part of Asia proved great failures, and misery and poverty following in their train brought insecurity to the front. Murder and robbery are heard of everywhere, and amongst the first victims was my nephew (not myself, as announced in THE GARDEN), who for a week was in the hands of brigands. Thank God, all's well that ends well. Now we are anxious to have rain. Here we are, almost at Christmas, and we can almost sit with our doors and windows open. The weather is lovely, the garden bright with all sorts of summer flowers, to which can be added such plants as Camellias, Azaleas, Hyacinths, &c., but what of next season's cereal crops? The thought is simply appalling. God grant He may hear the prayers of the poor peasants, who join together, irrespective of faith, in their public supplications for the much-wanted rain. Of course, after my description of the state of the country you can understand that collecting is not easy, but still I hope to plod along again next year. I hope you will not mind correcting in your journal the statement by Mr. Burbidge of my capture. Of course, few in England know, but the Whittall family is a patriarchal one, my mother, who is alive and well, counting a good many over 100 children, grandchildren, and great-grandchildren."

NOTES OF THE WEEK.

Phyllocactus Billardieri is a very showy kind, with large, handsome flowers of a deep rose, shading to pink at the edges. The large trumpet-shaped blossoms are just now as attractive as they are handsome and distinct. The tone of colour is quite exceptional.

Hippeastrum calyptratum var. *pallidum*.—This very distinct form may now be seen flowering in the No. 7 range in the Royal Gardens, Kew, the scape, which is nearly 2 feet high, carrying a pair of the curiously coloured flowers. The predominant shade is greenish, with occasional lines of white and a margin of creamy white.

Datura suaveolens.—The large, drooping blossoms of this species, though not abundantly produced at this season, are, nevertheless, showy and acceptable even where but a few are forthcoming. Formerly these plants were more largely grown, and under the name of *Brugmansia* were to be found in many sub-tropical arrangements in summer, the plants flowering in August and September.

O. honna trinervia.—There is a wide gap apparently between this rather tall-growing kind and the better-known *O. cheirifolia* that forms so striking a feature in the rock garden. The former species has a tree-like stem to 5 feet or 6 feet high, terminated by a tuft of pale glaucous leaves. From amid this dense head of distinct foliage the small golden flower-heads issue, borne on a three-forked stem and sufficiently long to clear the leaves.

The recent storm.—In the more exposed portions of Richmond Park large limbs of trees have been wrenched off during the storm of Monday night, whilst the fine old timber in Syon Park, the seat of the Duke of Northumberland, also suffered severely. At Kew Gardens a lot of damage was done to the trees, and at times the staff had considerable anxiety as to the safety of the high glass roofs of the great Palm house. The parks in London have suffered considerably, notably Greenwich Park, which is more exposed than any of the others. In Victoria Park, Dulwich Park, and La Lywell Park, Lewisham, several trees have been torn up.

Peristrophe speciosa.—For a good and showy flowering plant in the greenhouse or conservatory at this season the above-named species would be difficult to surpass. As a free-flowering bush of good habit and of easy culture this species, with its profusion of mauve-purple blossoms, is worthy of more attention than it receives. Large plants, nearly or quite 3 feet high and in considerable quantities, are now very attractive in the greenhouse at Kew.

Iris Bakeriana.—In a sunny position this gem among early-flowering Irises came into bloom a day or two before Christmas. Unfortunately, the weather has been such that the flowers are short-lived. Drenching rains and furious winds are too much for this exquisite little bloom. The blue and white flowers are, however, very beautiful while they last. Associated with early Snowdrops, *Iris Bakeriana* in a mass would form a delightful picture on a sunny day in winter.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

Poinsettias.—A very striking feature just now in the large succulent house at Kew is the number of these plants (which the modern botanist has now referred to *Euphorbia*) arranged at intervals throughout the structure. At this time of year flowering plants are not numerous in this department, so these *Euphorbias*, while in keeping and associating with other species of the genus, lend a little colour to the whole. In this comparatively cool place the plants long retain their brilliant bracts.

Cyclamen persicum var. *Papilio*.—What the future developments of this strain may be it is difficult now to foresee, and equally impossible to say whether such developments may be any improvement on the present high class strains so justly admired. Of the beauty of many of the best strains now in commerce there is little need to speak. These winged or feathered kinds, however, would appear to open out quite a new field. Already several years have elapsed since the first appearance of the feather in these flowers, so that, if slow, the advances are marked.

Early Irises.—This has so far been the most favourable season for those plants I can remem-

ber. *I. Histrio* opened its first flower on November 9, *I. alata* on the 13th, and they have flowered profusely and continuously ever since. *I. Bakeriana* opened on the 24th inst., while flowers of *I. stylosa* have been fairly plentiful since the middle of the month, or about two months earlier than last season. *I. persica Vogeliana* began to open on the 20th inst. I send you flowers of these. They vary much in colour; some of the Quaker grey and purples are charming.—T. SMYRN, *Newry*.

Aloe ciliaris.—Few species of *Aloe* are so free-flowering as this. For cutting, the long tubular blossoms, not unlike a rather long *Lachenalia* in appearance, are of a yellow shade and tinged with orange on the upper part. The prettily coloured flowers gather together on rather short, thick spikes of some 8 inches in length, and in their position close against the roof glass are rather attractive. This is as much due to the distinct colour as to the many spikes a good-sized example will produce. A capital example of this free-flowering species is now an attraction in the large succulent house at Kew.

Tibouchina (Lasiandra) macrantha.—There is perhaps no greenhouse flowering plant to vie with this when in flower. It is so at almost any season of the year, even when good flowering subjects are fairly abundant, and even more so in winter-time, when of necessity the number is greatly reduced. Most frequently the greater flush of flowers is produced during the autumn, but where a north aspect can be given the above, a large number of flowers may be regarded as more or less certain during winter. At any season the richly coloured flowers are welcome. Where a fair amount of roof space can be given this constitutes one of the best positions for it.

A new Rose.—M. Bonnaire, of Lyon-Monplaisir, has been awarded a medal for a perfect Rose called *Mme. Charretton* (a Tea). The flower opens well, is well made, and in colour varies between canary and orange-yellow. M. Bonnaire has already brought out a number of beautiful Roses, *Docteur Grill* to wit, a very handsome variety of Tea Rose, very good as a cut flower and for planting in masses; also *Souvenir de Victor Hugo*, in colour china rose, shaded with capuchin-yellow; also *Elisa Teugier*, a variety of the first order and a beautiful pure white. This last-named variety may be advantageously substituted for *Niphotos* as an open-air flower for cutting.

Senecio grandifolius.—From the specific name it may be assumed that this fine *Groundsel* has nothing but fine foliage to recommend it. Such, however, is not the case, as, apart from the well-proportioned leaves, which possibly are the largest of any species in this remarkable genus, there is a huge head of bloom sometimes 2 feet across. Well-developed plants of this species attain to 6 feet and sometimes 8 feet high, such plants producing a large flattish head of golden yellow. At this size, however, the plant is only suited to large structures, though smaller examples may be secured by restricting the root-room at potting time. As an attractive winter flowering species the plant is worthy of attention.

Galanthus Olgae Reginae.—As to this species, I beg to remind Mr. S. Arnott that we had two consecutive seasons very unfavourable to the growth of bulbs. After a year or two following their introduction, most bulbs conform to the conditions under which we condemn them to grow. If *Galanthus Olgae Reginae* is grown in a frame, not lifted or transplanted and kept dry for three months, it is sure to show its flowers in September, being the earliest of all Snowdrops. This quality, and nothing else, is its principal value. The Dutch growers can tell a sad tale this year about the difficulties of growing bulbs to a fair size in seasons like the one just past. Although I introduced *G. Olgae Reginae* to cultivation, yet I do not recommend it but for its early flowering. Of all *Galanthus*es I have ever grown, *G. caucasicus grandis*, from Stralfun-

House, seems to my idea the very best. — MAX LEICHTLIN, *Baden-Baden*.

Cyrtanthus McKeui. — The pretty Cape flowering bulbs composing this group, though exceedingly attractive in appearance, and of easy culture and free-flowering withal, are all too rarely seen in cultivation. Like many other Amaryllids, these require but little attention for several months, and the needful labour at any time is but slight. The arching tubular blossoms rarely fail to attract attention, the individual blossoms curving in an arc shape from the summit of the slender scape. The kind mentioned has blooms of almost snowy whiteness, sweet-scented, and each about 3 inches long. Several of them are produced on each stem. Usually the flowering period follows closely upon that of Nerine. A course of treatment similar to that for *Hemanthus* or *Nerineis* quite suitable to the members of the above group.

Tulip Vermilion Brilliant. — Very few varieties of Tulip approach this in the shape of its flowers. It is almost unique in point of colour. Yet another point which most Tulips lack is the thin, slender stem. This materially assists a more graceful bearing. Many kinds have stems so thick and rigid that in a vase they are little short of clumsy. For this reason alone a few more of a type similar to the above would be welcomed. The above variety is a capital one for forcing, and while somewhat more expensive than ordinary forcing kinds, will not fail to give satisfaction at flowering time. Slightly smaller in flower, and the buds more graduated and tapering to the tip, this kind more nearly approaches perfection in its flowers than any other of the bedding sorts at present in commerce.

Asparagus Sprengeri compactus. — This distinct form, which received a first-class certificate from the floral committee of the Royal Horticultural Society at its last meeting for the year 1898, is a plant of considerable promise. Singularly enough, there are now three gradations of

this species, all sufficiently good, distinct, and ornamental to be included in one collection. The type has long drooping branches that extend to several feet in length. Next to this is the variety *A. S. densissimus*, which, coupled with a more densely set growth, is considerably restricted in its drooping, being but barely half so long as the original. This intermediate kind, as it may well be termed, is a most valuable plant, though it does not appear to be generally known. Lastly, there is the variety *A. S. compactus*. This, indeed, is more widely distinct than is *A. S. densissimus*, as the latter may without comparison be taken for a partially developed plant of the original species. Such, however, could not happen in the case of *A. S. compactus*, which produces a veritable cushion of its fronds, that gracefully arch over each other to a length of about 15 inches in the longest growths. It is in this respect just long enough to perfectly hide the receptacle containing its many tuberous roots, the habit of growth very dense, and the latest-formed growths but half the length of the earliest. If raised above brightly coloured Crotons or the like, or even as a centre-piece for the dinner-table, its effect would be excellent.

PUBLIC GARDENS.

New park for Ealing. — At a special meeting of the Ealing Urban District Council, under the presidency of Sir E. Montague Nelson, fourteen out of sixteen members being present, it was resolved to accept the offer of Sir Spencer Walpole to sell to the Council, for the purposes of a public park, the Manor House estate. The estate comprises a mansion at present occupied by Miss Perceval, with grounds attached covering about thirty-one acres, the purchase price of which is £40,000. The sale is subject to the life interest of Miss Perceval, and the Council will not obtain possession till that lady's death. The

motion was adopted by the votes of eleven members, three of those present not voting.

The weather in West Herts. — The weather remained cold until the 25th, when a change to much warmer conditions took place. On the first three days of the week the temperature in shade never exceeded 41°, and on the same three nights the exposed thermometer registered from 11° to 14° of frost. On the 27th, however, the reading in the thermometer screen rose to 53°, while that on the grass never fell lower than 40°. At both 2 feet and 1 foot deep the ground is at the present time about 4° warmer than their respective averages for the end of December. Shortly before midday on the 27th rain and hail fell for five minutes at the mean rate of nearly an inch an hour. — E. M., *Berkhamsted*.

Royal Gardeners' Orphan Fund. — A meeting was held on Tuesday last, Mr. Wm. Marshall in the chair. After the usual routine the secretary announced the receipt of the following special donations: Altrincham Gardeners' Society, £15 10s.; Scottish Horticultural Association, £15; Canterbury Hospital and Charities Fête, £5; H. Herbst, Richmond, proceeds of box, £5; Chislehurst Gardeners' Society, £3 14s.; Panshurst Gardeners' Society, £3 3s.; Mr. Selway, Betteshanger, £2 10s.; and several other smaller amounts. The nomination forms were received, there being nineteen applicants, who were found eligible and put on the list. The election of officers for the ensuing year was preceded with, there being four retiring members, whose places have to be filled. The secretary, Mr. Barron, announced that he would not seek reelection on this occasion on account of the unsatisfactory state of his health. The committee expressed much regret at the loss of Mr. Barron's services, and appointed a sub-committee to make arrangements for the appointment of a new secretary.
